Humla v0.3

Overview

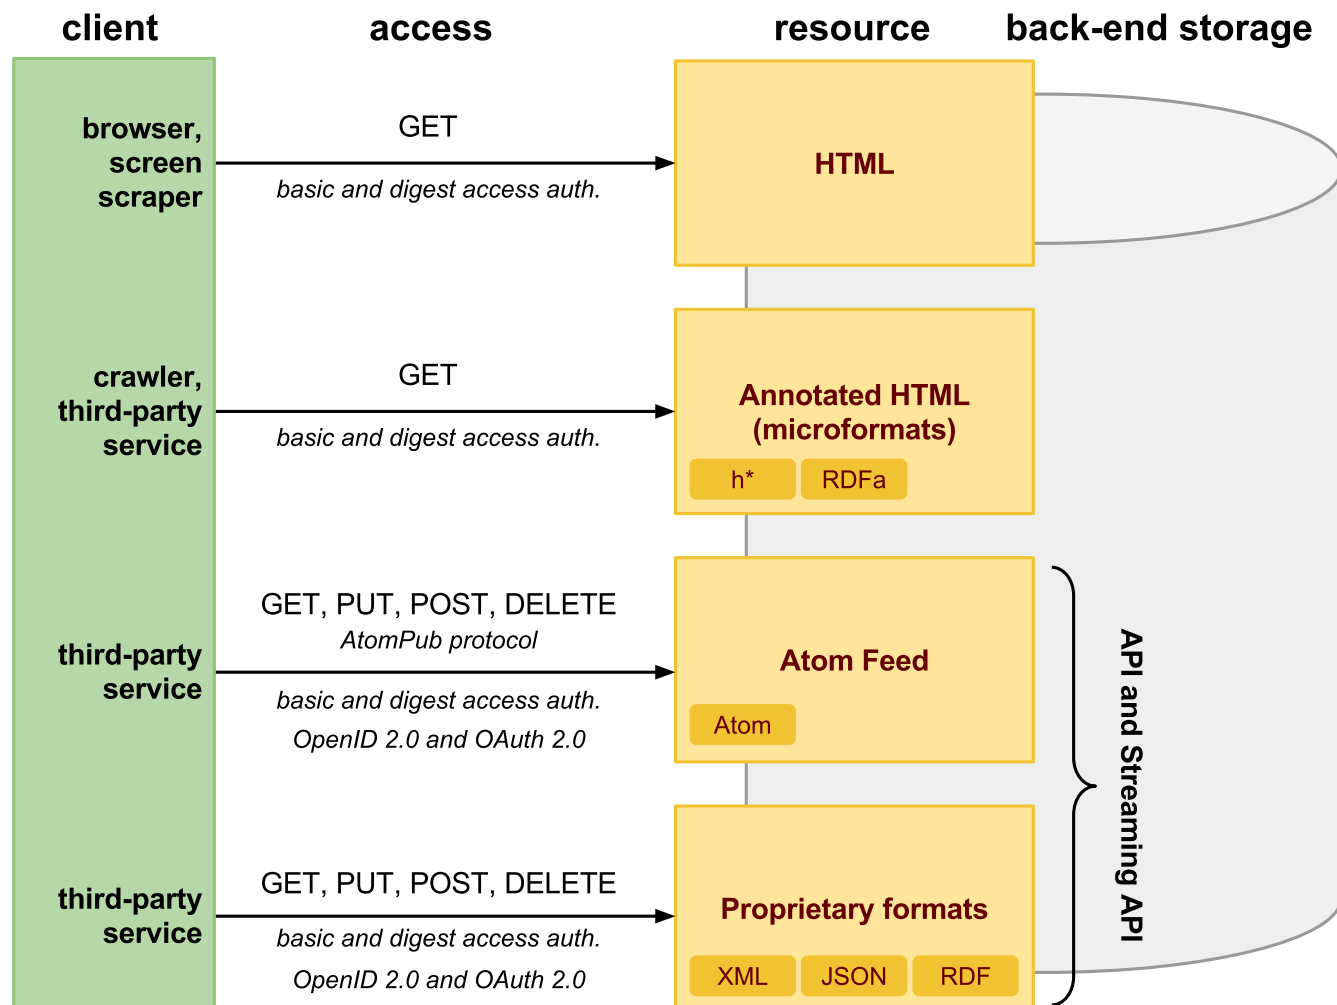

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
- OpenID

Web Service Security Concepts

- Securing the client-server communication
 - *Message-level security*
 - *Transport-level security*
- Ensure
 - *Authentication* – *verify a client's identity*
 - *Authorization* – *rights to access resources*
 - *Message Confidentiality* – *keep message content secret*
 - *Message Integrity* – *message content does not change during transmission*
 - *Non-repudiation* – *proof of integrity and origin of data*

Data on the Web

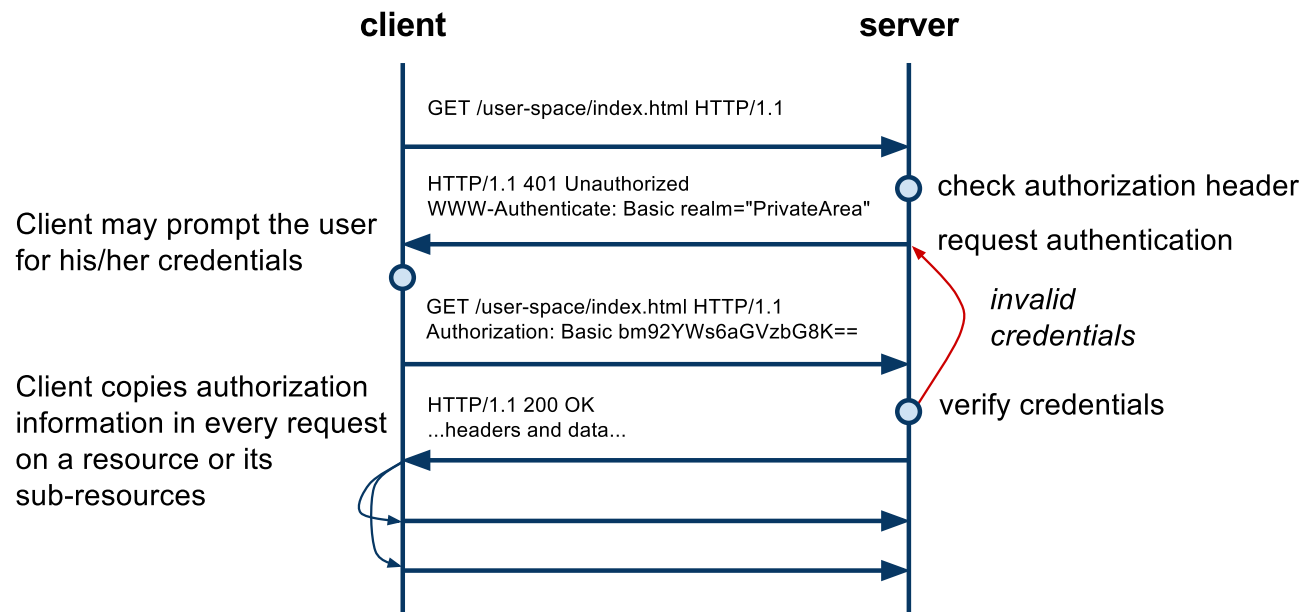

Overview

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
- OpenID

Authentication and Authorization

- Authentication
 - *verification of user's identity*
- Authorization
 - *verification that a user has rights to access a resource*
- Standard: HTTP authentication
 - *HTTP defines two options*
 - *Basic Access Authentication*
 - *Digest Access Authentication*
 - *They are defined in*
 - *RFC 2616: Hypertext Transfer Protocol – HTTP/1.1*
 - *RFC 2617: HTTP Authentication: Basic and Digest Access Authentication*
- Custom/proprietary: use of cookies

Basic Access Authentication

- Realm
 - *an identifier of the space on the server (~ a collection of resources and their sub-resources)*
 - *A client may associate a valid credentials with realms such that it copies authorization information in requests for which server requires authentication (by **WWW-Authenticate** header)*

Basic Access Authentication – Credentials

- Credentials
 - *credentials are base64 encoded*
 - *the format is: username:password*
- Comments
 - *When SSL is not used, the password can be read*
 - *An attacker can repeat interactions*

Digest Access Authentication

- RFC 2617 – Basic and Digest Access Authentication
 - *No password between a client and a server but a hash value*
 - *Simple and advanced mechanisms (only server-generated nonce value – replay-attacks or with client-generated nonce value)*
- Basic Steps
 1. *Client accesses a protected area*
 2. *Server requests authentication with WWW-Authenticate*
 3. *Client calculates a response hash by using the realm, his/her username, the password, and the quality of protection (QoP) and requests the resource with authorization header*

Nonce and QoP

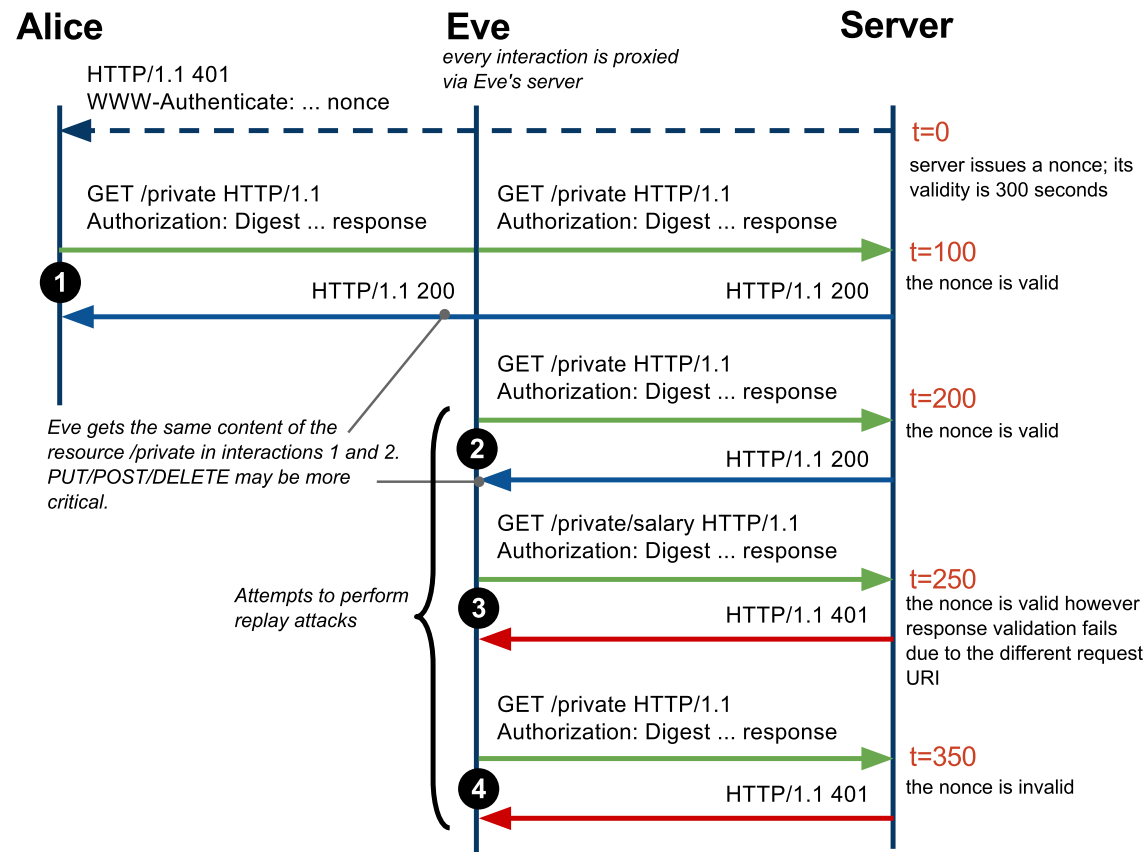

- Nonce
 - *A value to identify an interaction that should occur only once*
 - **nonce** – *generated by the server*
 - *may have a time period for which the nonce is valid*
 - *may be computed using client IP, ETag of the resource, etc.*
 - *this limits chances for the replay attack.*
 - **cnonce** – *generated by the client*
- QoP – quality of protection
 - *Further improvements to prevent replay attacks and enables non-repudiation*

Algorithms

- Algorithm for **response** value of **authorization** header
 - *No quality of protection (qop is missing or qop=none)*
 - *limits chances of replay-attacks*
 - *with quality of protection (qop=auth)*
 - *with quality of protection for message integrity (qop=auth-int)*
 - *enables non-repudiation (i.e., proof of integrity and origin of data)*

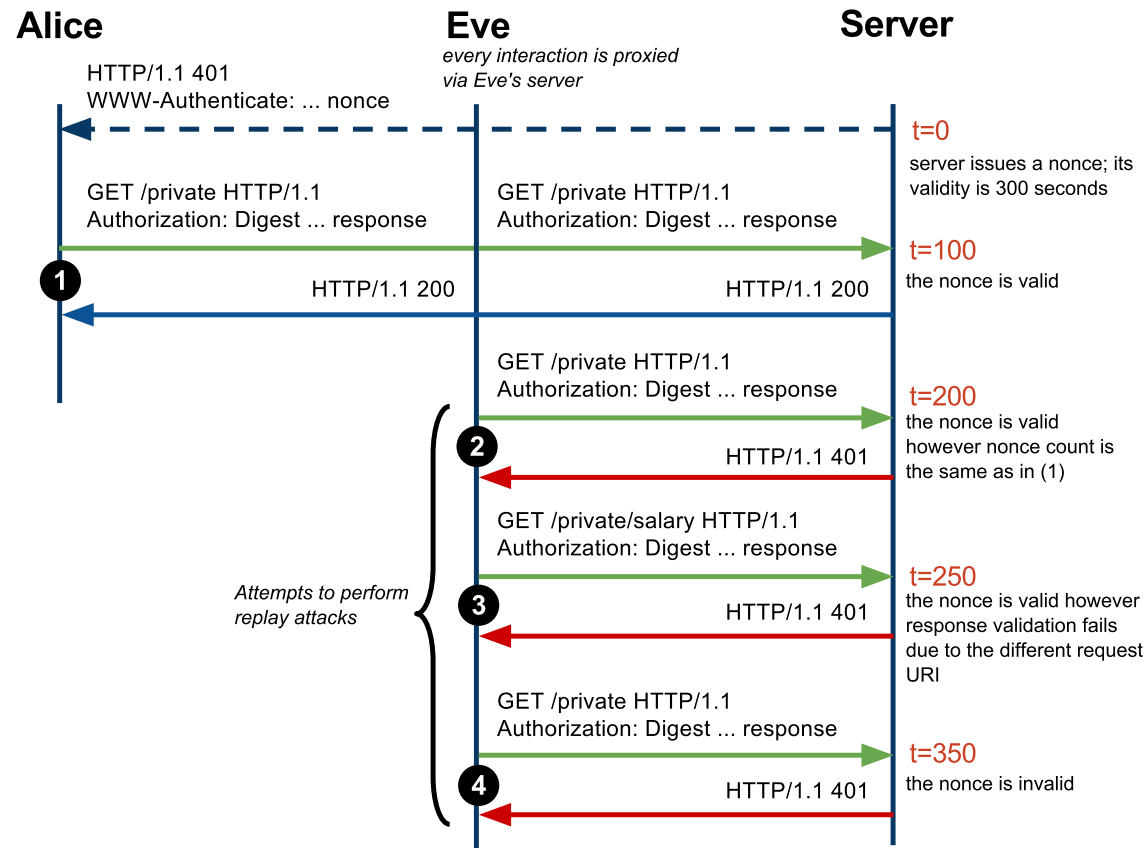

Replay Attack

- Replay Attack Scenario (quality of protection is **none**)
 - The communication is not encrypted (i.e., no use of HTTPS)
 - Eve listens to the Alice's communication (e.g. on a proxy server)
 - Eve resends requests with headers from Alice's requests

Replay Attack (Cont.)

- Replay Attack Scenario (quality of protection is **auth** or **auth-int**)
 - **nonceCount** should be incremented in every request to a response of the nonce value from the server

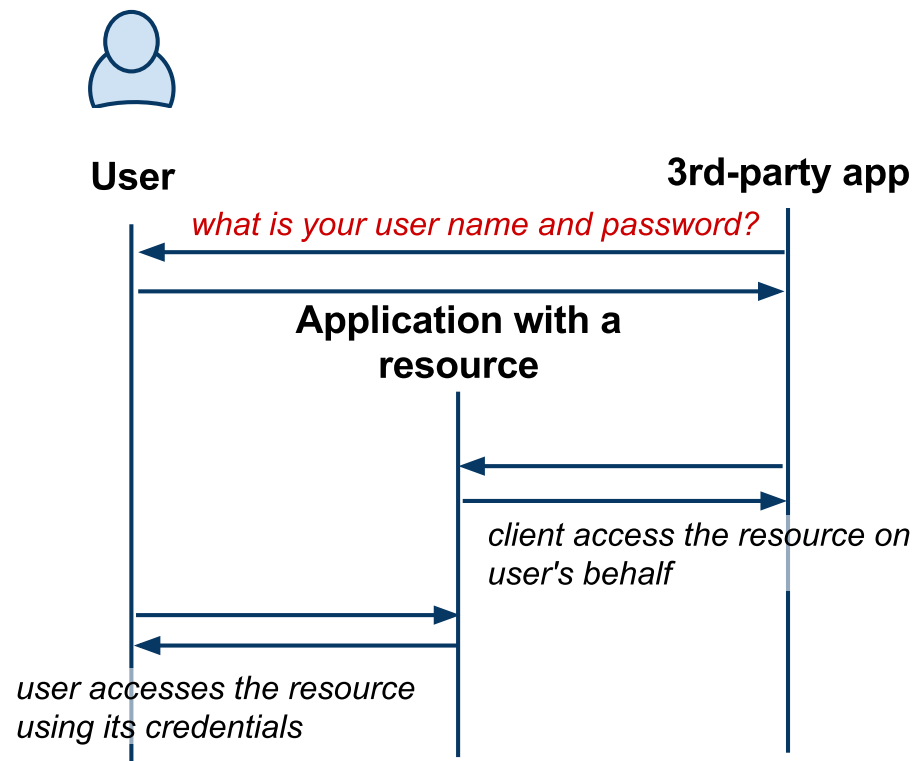

Overview

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
 - *Client-side Web Apps*
 - *Server-side Web Apps*
 - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

Motivation

- Cloud Computing – Software as a Service
 - *Users utilize apps in clouds*
 - *they access **resources** via Web browsers*
 - *they store their data in the cloud*
 - *Google Docs, PicasaWeb, etc.*
 - *The trend is that SaaS are open*
 - *can be extended by 3rd-party developers through APIs*
 - *attract more users ⇒ increases value of apps*
 - *Apps extensions need to have an access to users' data*
- Need for a new mechanism to access resources
 - *Users can grant access to third-party apps without exposing their users' credentials*

When there is no OAuth

- Users must share their credentials with the 3rd-party app
- Users cannot control what and how long the app can access resources
- Users must trust the app
 - *In case of misuse, users can only change their passwords*

OAuth 2.0 Protocol

- OAuth Objectives
 - *users can grant access to third-party applications*
 - *users can revoke access any time*
 - *supports:*
 - *client-side web apps (implicit grant),*
 - *server-side apps (authorization code), and*
 - *native (desktop) apps (authorization code)*
- History
 - *Initiated by Google, Twitter, Yahoo!*
 - *Different, non-standard protocols first: ClientLogin, AuthSub*
 - *OAuth 1.0 – first standard, security problems, quite complex*
 - *OAuth 2.0 – new version, not backward compatible with 1.0*
- Specifications and adoption
 - *OAuth 2.0 Protocol* [🔗](#)
 - *OAuth 2.0 Google Support* [🔗](#)

Terminology

- **Client**
 - *a third-party app accessing resources owned by **resource owner***
- **Resource Owner** (also user)
 - *a person that owns a resource stored in the **resource server***
- **Authorization and Token Endpoints**
 - *endpoints provided by an **authorization server** through which a **resource owner** authorizes requests.*
- **Resource Server**
 - *an app that stores resources owned by a **resource owner** (e.g., pictures in Google PicasaWeb)*
- **Authorization Code**
 - *a code that a **client** uses to request **access tokens** to access resources*
- **Access Token**
 - *a code that a **client** uses to access resources*

Overview

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
 - *Client-side Web Apps*
 - *Server-side Web Apps*
 - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

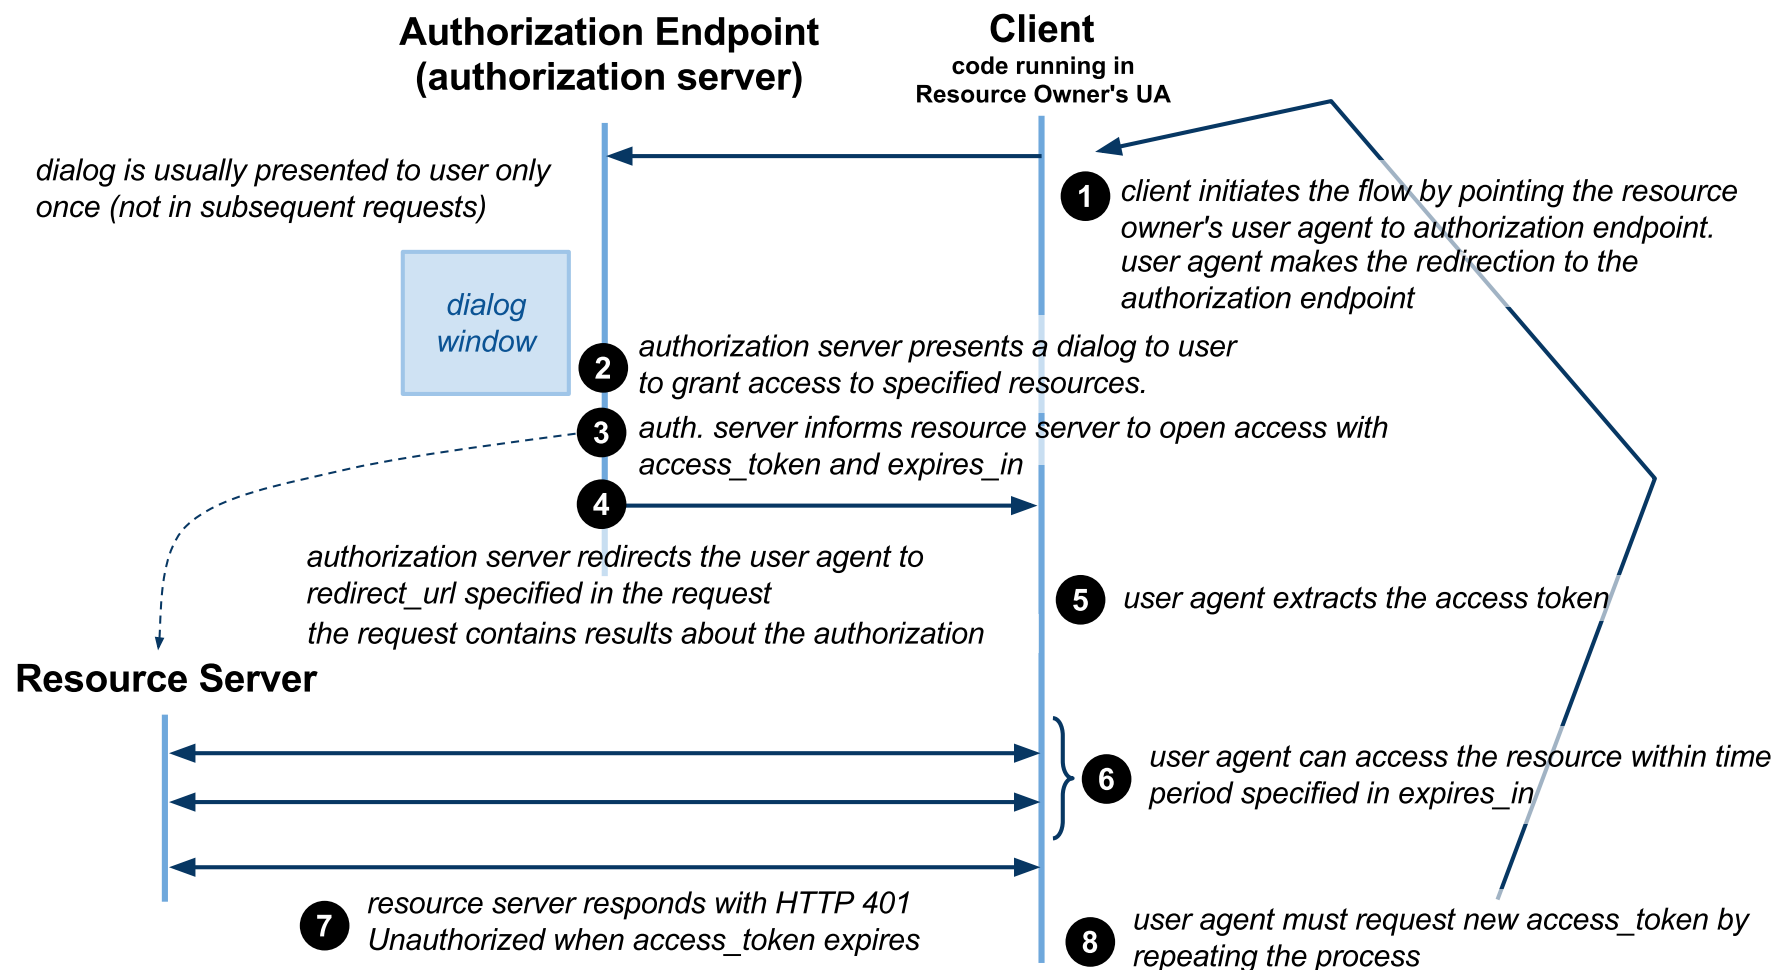

Client-side Web Apps

- Simplified version of OAuth 2.0 protocol
 - *JavaScript/AJAX apps running in a browser*
 - *Apps that cannot easily "remember" app state*
 - *limited number of interactions*
- Architecture
 - *User-agent processes a javascript/HTML code from the client*
 - *No need of authorization code*
- Basic Steps
 - *A client redirects a user agent to the authorization endpoint*
 - *A resource owner grants an access to the client or rejects the request*
 - *Authorization server provides an **access_token** to the client*
 - *Client access the resource with the **access_token***
 - *When the token expires, client requests new token*

Demo – List of Contacts

- Display your Google contacts
 - *this demo requests authorization from you to access your Google contacts using client-side OAuth 2.0 protocol and then displays the contacts below. In order to transfer **access_token** from authorization window, it stores the **access_token** in a cookie.*
 - **access_token**
 - *Show contacts or revoke access*

Client-side Web Apps Protocol

Redirection – Step 1

- Methods and Parameters
 - *Methods: GET or POST*
 - *example authorization endpoint url (Google):*
`https://accounts.google.com/o/oauth2/auth`
 - *query string parameters or application/x-www-form-urlencoded*
 - `client_id` – *id of the client that was previously registered*
 - `redirect_uri` – *an URI that auth. server will redirect to when user grants/rejects*
 - `scope` – *string identifying resources/services to be accessed*
 - `response_type` – *type of the response (token or code)*
 - `state` (optional) – *state between request and redirect*
 - *Example*

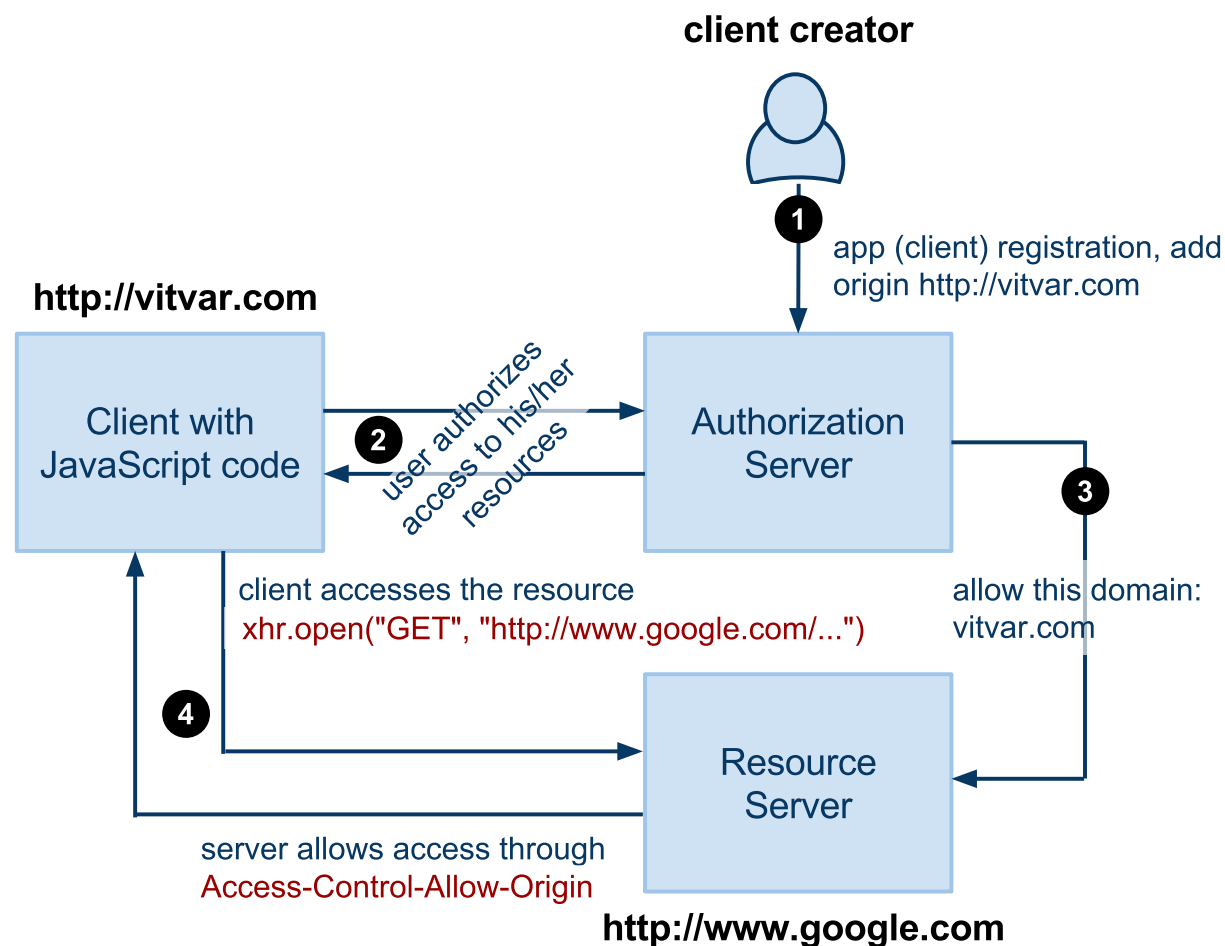

Callback – steps 4 and 5

- Resource owner grants the access
 - *authorization server calls back `redirect_uri`*
 - *client parses URL in JavaScript (Step 5)*
 - *extracts `access_token` and `expires_in` (by using `window.location.hash`)*
 - *Example:*
- Resource owner rejects the access
 - *authorization server calls back `redirect_uri` with query string parameter `error=access_denied`*
 - *Example:*

Accessing Resources – Step 6

- Request
 - *client can access resources defined by scope*
 - *resources' URIs defined in a particular documentation*
 - *Example Google Contacts*
 - *to access all users' contacts stored in Google*
 - *scope is `https://www.google.com/m8/feeds`*
 - *Query string parameter `oauth_token`*
 - *HTTP Header `Authorization`*
 - *The client can do any allowed operations on the resource*
- Response
 - *Success – `200 OK`*
 - *Error – `401 Unauthorized` when token expires or the client hasn't performed the authorization request.*

Cross-Origin Resource Sharing

— see *Same Origin and Cross-Origin* for details

Example Application Registration

API Access

Billing

Reports

Quotas

API Access

To prevent abuse, Google places limits on API requests. Using a valid OAuth token or API key allows you to exceed anonymous limits by connecting requests back to your project.

Authorized API Access

OAuth allows users to share specific data with you (for example, contact lists) while keeping their usernames, passwords, and other information private. [Learn more](#)

Branding information

The following information is shown to users whenever you request access to their private data.

Product name: w20-test

Google account: t.vitvar@gmail.com

[Edit branding information...](#)

Client ID for web applications

Client ID: 621535099260.apps.googleusercontent.com

Client secret: RxWM917Sv-7cyfWMW7KhNV9R

Redirect URIs: http://vitvar.com/examples/oauth/callback.html

JavaScript origins: http://example.org

[Create another client ID...](#)

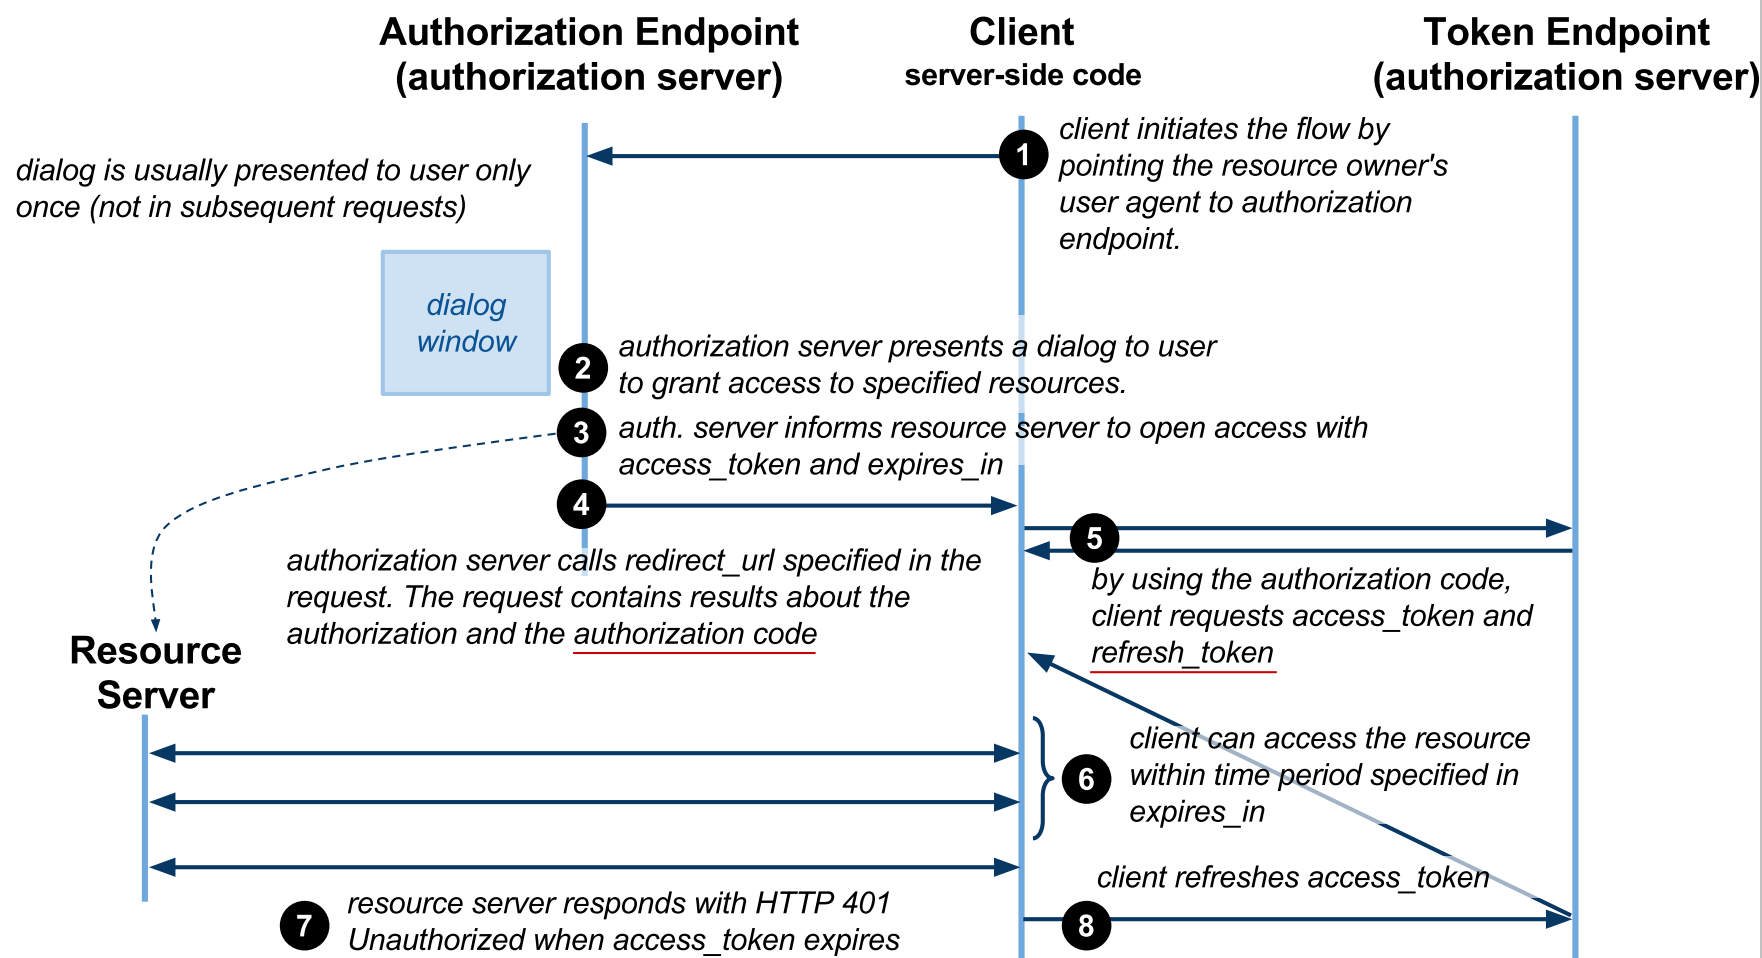

Overview

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
 - *Client-side Web Apps*
 - *Server-side Web Apps*
 - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

Server-side Web Apps

- Additional interactions
 - *server-side code (any language), the app can maintain the state*
 - *additional interactions, authorization code*
- Architecture
 - *Client at a server requests, remembers and refresh access tokens*
- Basic steps
 - *Client redirects user agent to the authorization endpoint*
 - *Resource owner grants access to the client or rejects the request*
 - *Authorization server provides **authorization code** to the client*
 - *Client requests **access and refresh tokens** from the auth. server*
 - *Client access the resource with the access token*
 - *When the token expires, client refreshes a token with refresh token*
- Advantages
 - *Access tokens not visible to clients, they are stored at the server*
 - *more secure, clients need to authenticate before they can get tokens*

Server-side Web Apps Protocol

Redirection – Step 1

- Methods and Parameters
 - *same as for client-side app, except `response_type` must be `code`*
- Example

Callback + Access Token Request – steps 4, 5

- Callback
 - *authorization server calls back* `redirect_uri`
 - *client gets the* `code` *and requests* `access_token`
 - *example (resource owner grants access):*
`http://humla.vitvar.com/slides/w20/examples/oauth/callback.html?code=4/P7...`
 - *when user rejects → same as client-side access*
- Access token request
 - `POST` *request to token endpoint*
→ *example Google token endpoint:*
`https://accounts.google.com/o/oauth2/token`

Access Token (cont.)

- Access token response
 - *Token endpoint responds with `access_token` and `refresh_token`*
- Refreshing a token
 - *`POST` request to the token endpoint with `grant_type=refresh_token` and the previously obtained value of `refresh_token`*
- Accessing a resource is the same as in the client-side app

Overview

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
 - *Client-side Web Apps*
 - *Server-side Web Apps*
 - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

Why new version?

- OAuth 1.0 in brief
 - *security not based on SSL*
 - *client must sign every request using a defined algorithm*
 - *e.g., public-private key signatures by RSA*
 - *More complex to be implemented by clients*
 - *although client libraries exist*
 - *not suitable for JavaScript-based clients*
- OAuth 2.0 simplifies the process
 - *SSL is required for all communications to generate the token*
 - *Signatures are not required for the actual API calls once the token has been generated*
 - *SSL is also strongly recommended here*
 - *supports various clients including JavaScript and mobile*

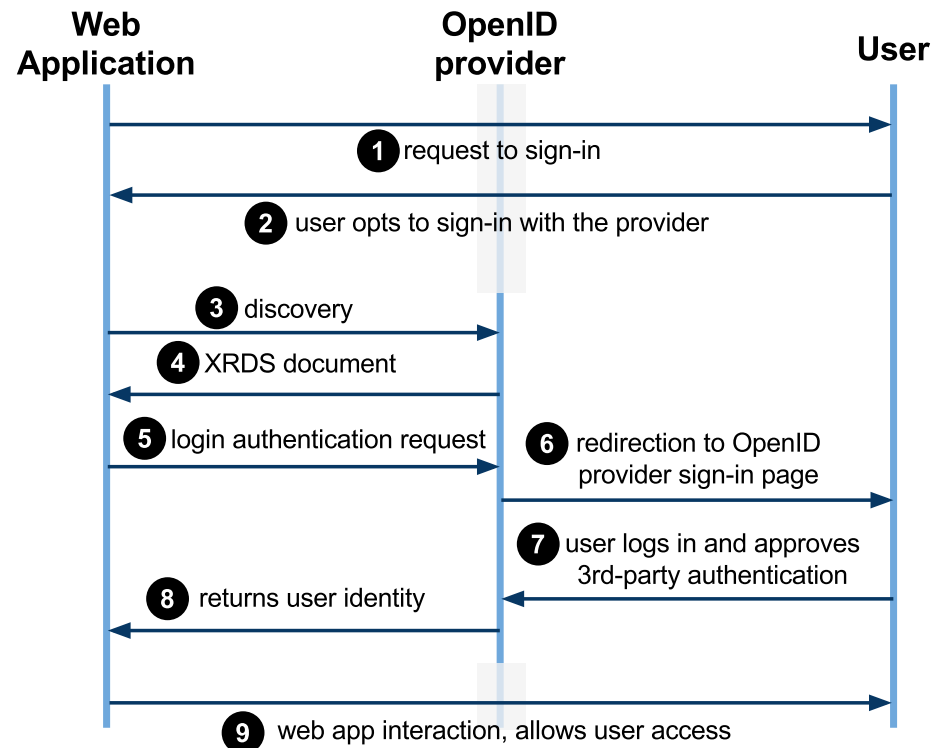

Overview

- Security Concepts
- Authentication and Authorization
- OAuth 2.0
- OpenID

OpenID Protocol

- Motivation – many user accounts
 - *users need to maintain many accounts to access various services*
 - *multiple passwords problem*
- Objectives
 - *allows apps to utilize an OpenID provider*
 - *a third-party authentication service*
 - *federated login*
 - *users have one account with the OpenID provider and use it for apps that support the provider*
- OpenID providers
 - *it is a protocol, anybody can build a provider*
 - *Google, Yahoo!, Seznam.cz, etc.*
- Specification
 - *OpenID Protocol* 

Interaction Sequence

- Discovery – discovery of a service associated with a resource
- XRDS – eXtensible Resource Descriptor Sequence
 - *format for discovery result*
 - *developed to serve resource discovery for OpenID*
 - *Web app retrieves endpoint to send login authentication requests*

Login Authentication Request – Step 5

- Example Google OpenID provider
- Parameters
 - **ns** – *protocol version (obtained from the XRDS)*
 - **mode** – *type of message or additional semantics (**checkid_setup** indicates that interaction between the provider and the user is allowed during authentication)*
 - **return_to** – *callback page the provider sends the result*
 - **realm** – *domain the user will trust, consistent with **return_to***
 - **assoc_handle** – *"log in" for web app with openid provider*
- * *Not all fields shown, check the OpenID spec for the full list of fields and their values*

Login Authentication Response – Step 8

- User logs in successfully
 - Web app will use **identity** to identify user in the application
 - response is also signed using a list of fields in the response (not shown in the listing)
- User cancels
 - * Not all fields shown, check the OpenID spec for the full list of fields and their values
