Humla v0.3

Overview

- Mashups and XHR
- Security Mechanisms
- JSON and JSONP

Mashups

- Web application hybrid/Web 2.0 application
 - *Uses APIs of two or more applications to provide new value-added functionality*
- Types
 - *Data mashup – integration/aggregation of data (read only)*
 - *Service mashup – more sophisticated workflows (read, write)*
 - *Visualization – involves UI, e.g., third-party data displayed on the Google map*
- Client-Server View
 - *client-side mashups (mainly in a browser)*
 - *JavaScript, Dynamic HTML, AJAX, JSON/JSONP*
 - *server-side mashup*
 - *server-side integration of services and data*
 - *third-party programming languages, very typical, nothing new*
 - *specialized environments: Google AppsScript, Yahoo Pipes*
- **Web Apps developments will all be about mashups!**

XMLHttpRequest (XHR)

- Interface to utilize HTTP protocol in JavaScript
 - *standardized by Web Applications WG [↗](#) at W3C*
 - *basis for AJAX*
 - *Asynchronous JavaScript and XML*
- Typical usage
 1. *Browser loads a page that includes a script*
 2. *User clicks on a HTML element*
 - *it triggers a JavaScript function*
 3. *The function invokes a service through XHR*
 - *same origin policy, cross-origin resource sharing*
 4. *The function receives data and modifies HTML in the page*

XHR Interface – Key Methods and Properties

- Method and properties of XHR object
 - **open**, *opens the request, parameters:*
 - method** – *method to be used (e.g. GET, PUT, POST),*
 - url** – *url of the resource,*
 - asynch** – *true to make asynchronous call,*
 - user, pass** – *credentials for authentication.*
 - **onReadyStateChange** – *JavaScript function object, it is called when **readyState** changes (uninitialized, loading, loaded, interactive, completed).*
 - **send, abort** – *sends or aborts the request (for asynchronous calls)*
 - **status, statusText** – *HTTP status code and a corresponding text.*
 - **responseText, responseXML** – *response as text or as a DOM document (if possible).*
 - **onload** – *event listener to support server push.*
- See XMLHttpRequest (W3C) [🔗](#), or XMLHttpRequest (Mozilla reference) [🔗](#) for a complete reference.

How XHR works

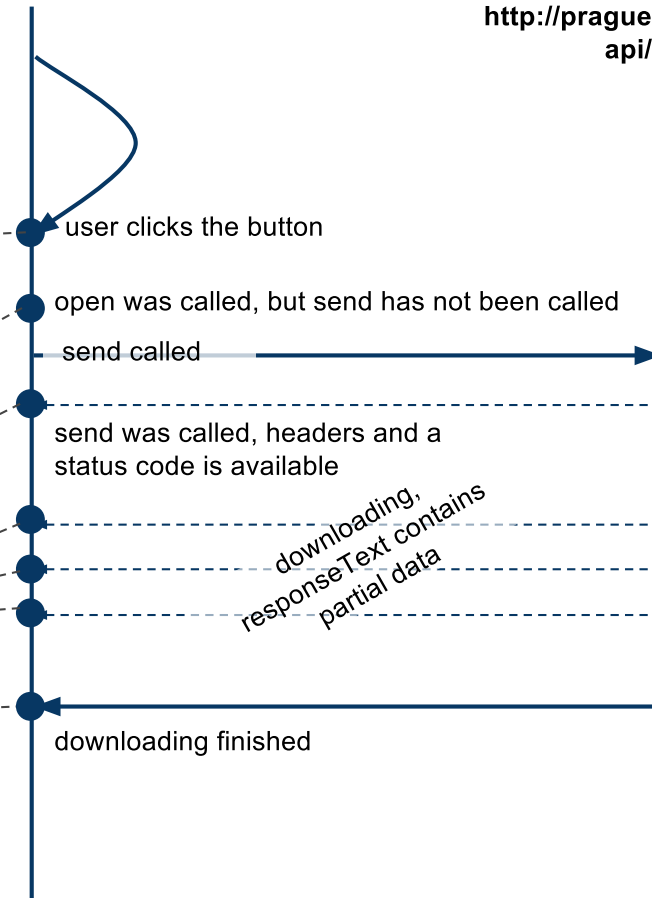

HTML with JavaScript code

was loaded as a response to `http://prague.example.org/`

```
...  
<input type="button" value="Show Prague!" onclick="click()" />  
  
<script type="text/javascript">  
  
xhr = new XMLHttpRequest();  
  
function click() {  
  xhr.open("GET", "http://prague.example.org/api/data", true);  
  xhr.onreadystatechange = stateChanged;  
  xhr.send();  
}  
  
function stateChanged() {  
  if (xhr.readyState == 1) { // loading  
    ...  
  }  
  if (xhr.readyState == 2) { // loaded  
    ...  
  }  
  if (xhr.readyState == 3) { // interactive  
    ...  
  }  
  if (xhr.readyState == 4) { // completed  
    ...  
  }  
}  
}  
</script>
```

Browser

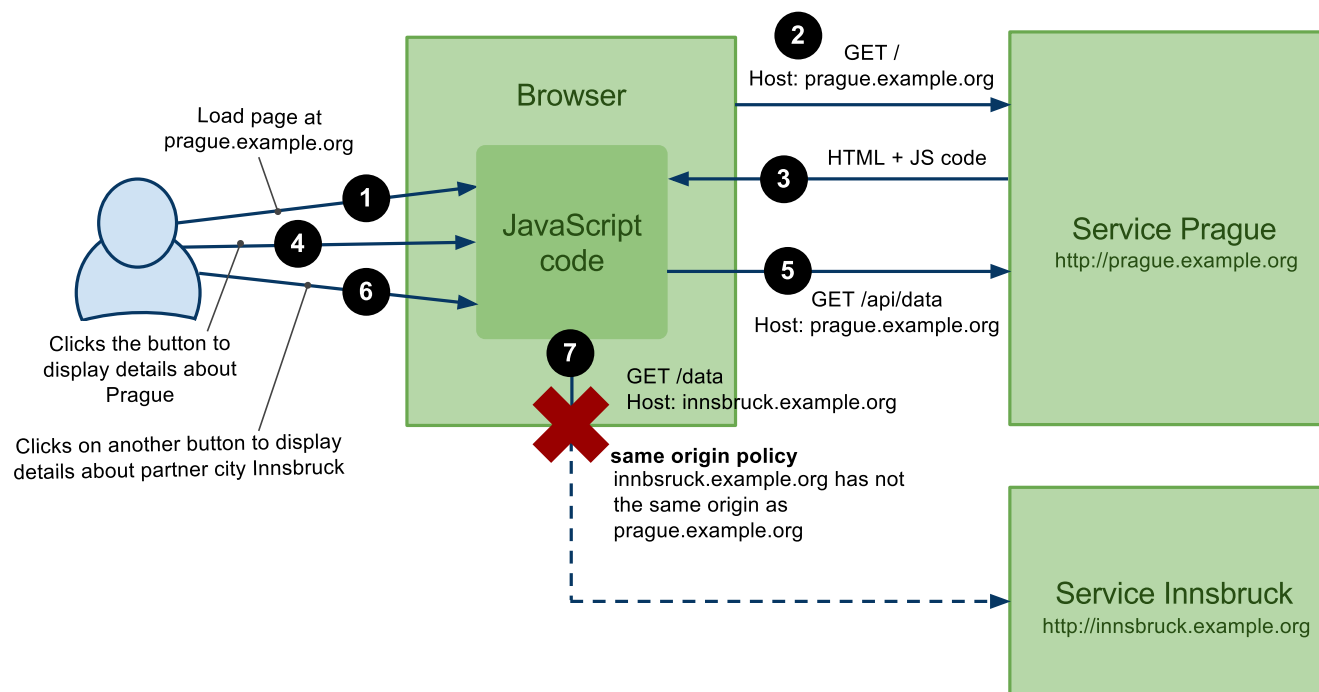

Resource at
`http://prague.example.org/
api/data`

Overview

- Mashups and XHR
- **Security Mechanisms**
 - *Scripting Attacks*
 - *Cross-origin Resource Sharing Protocol (CORS)*
- JSON and JSONP

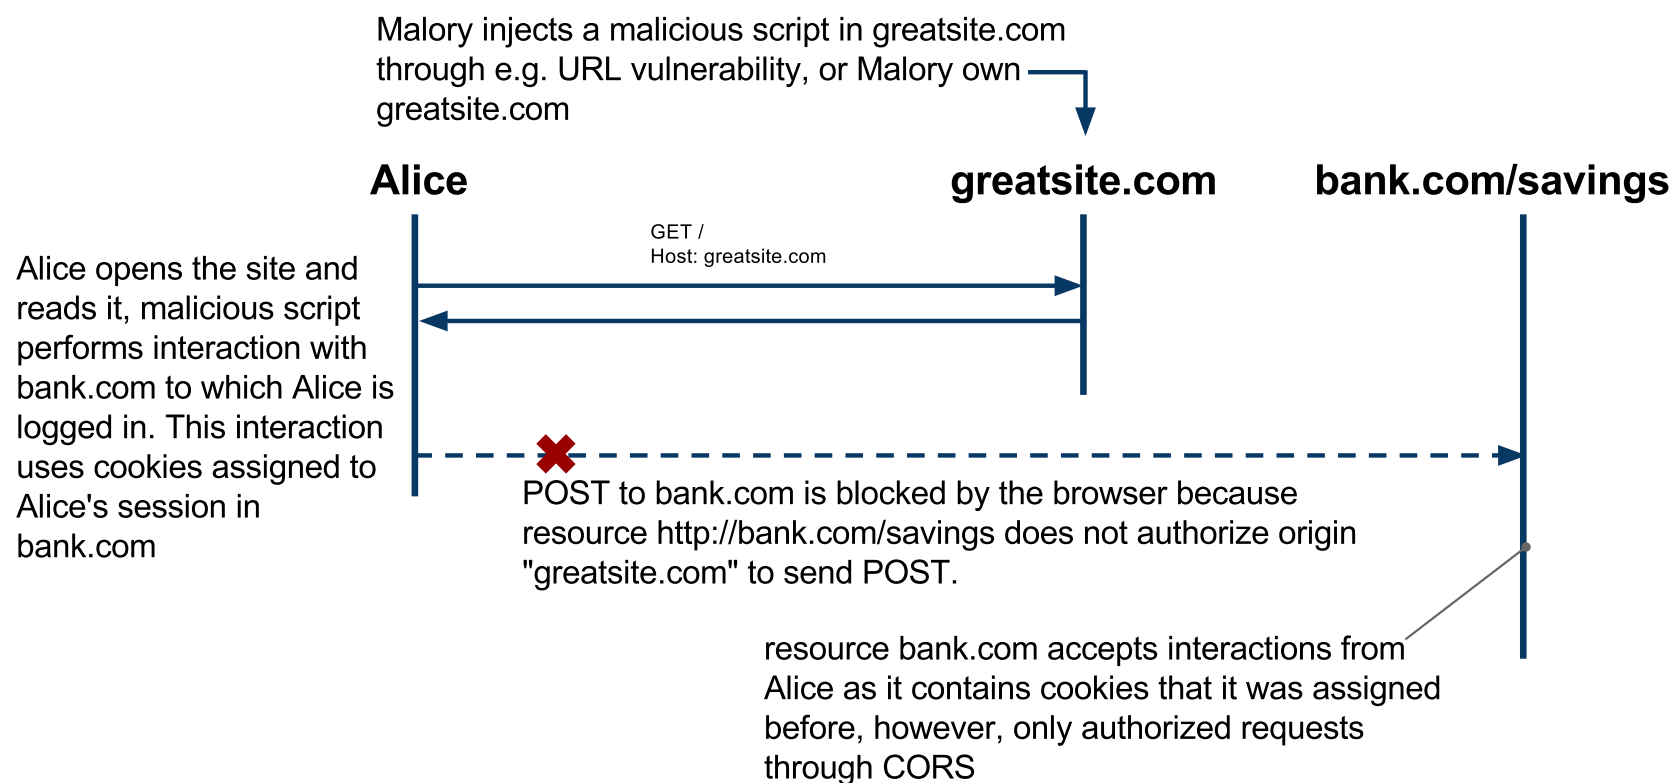

Same Origin Policy

- JavaScript code can only access resources on the same domain
 - *XHR to GET, POST, PUT, UPDATE, DELETE*
 - Browsers apply **same origin policy**
- Solutions
 - *JSON and JSONP (GET only)*
 - *Cross-origin Resource Sharing Protocol (CORS)*

Why Same Origin Policy?

- Without the same origin policy, the following POST would be possible

Overview

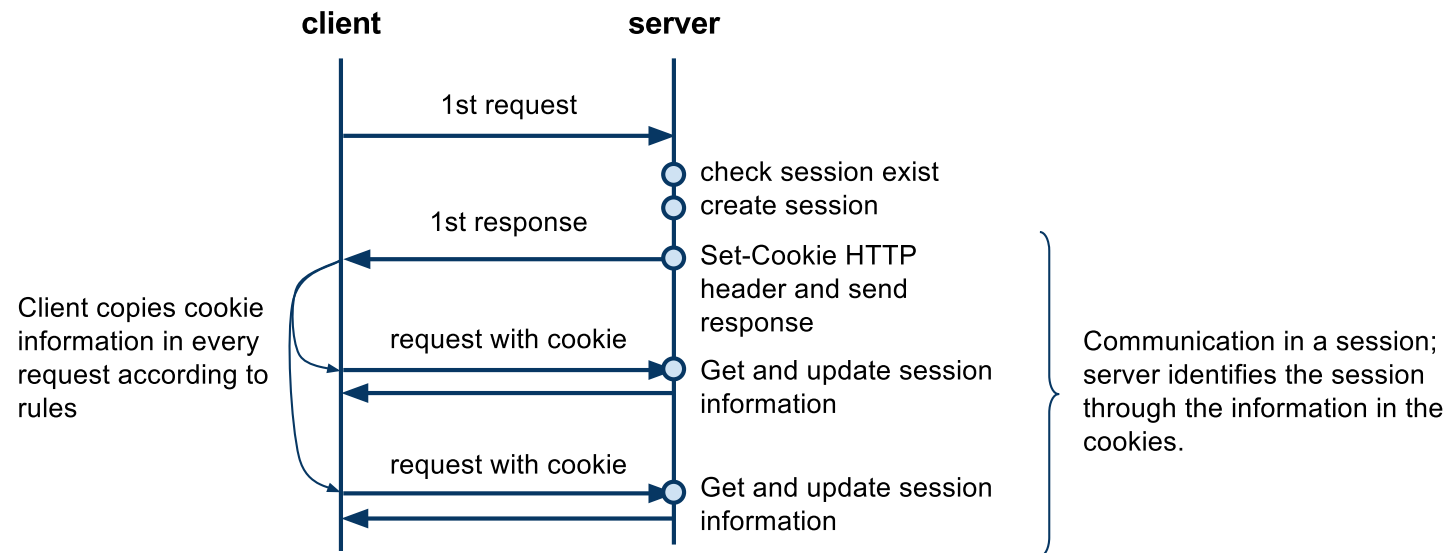

- Mashups and XHR
- Security Mechanisms
 - *Scripting Attacks*
 - *Cross-origin Resource Sharing Protocol (CORS)*
- JSON and JSONP

Overview

- Scripting Attacks
 - *Intruders make users perform action that has side effects on their resources*
 - *Intruders inject malicious code to Web pages*
- Roles in Security Scenarios
 - *Alice, Bob*
 - *Normal users, usually Alices wants to send a message to Bob or Alice accesses a Bob's site.*
 - *Eve*
 - *A user with bad intentions, usually a passive attacker.*
 - *Mallory*
 - *An active attacker, usually sends a link to a page with malicious code.*

Recall: State management in HTTP

- Request-response interaction with cookies
 - *Session is a logical channel maintained by the server*

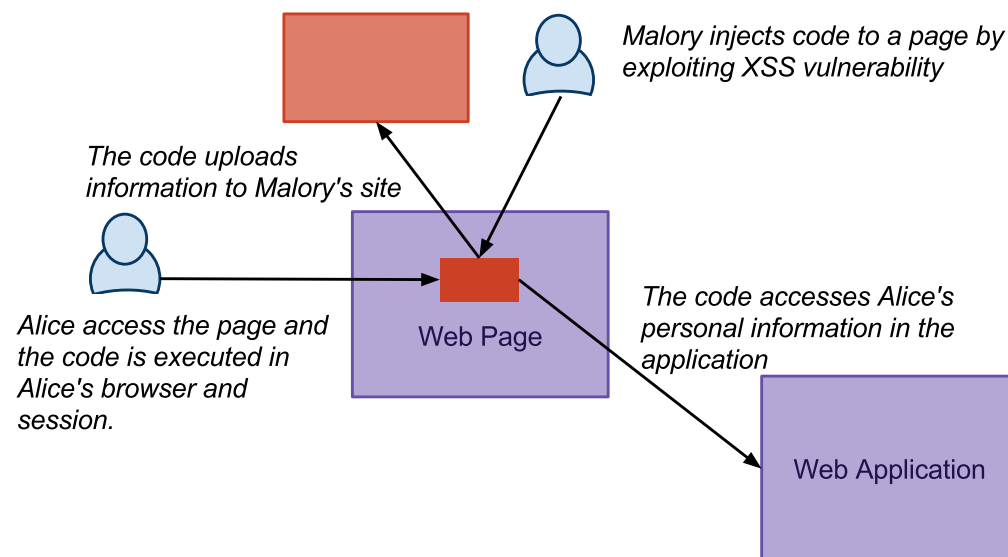

- Stateful Server
 - *Server remembers the session information in a server memory*
 - *Server memory is a non-persistent storage, when server restarts the memory content is lost!*

Cross-site Request Forgery (CSRF)

- Exploits a trust of a website in a user's browser
- Scenario
 1. Mallory sends a link to Alice (in an email, in a chat, etc.)
 - The link points to a page that has HTML code with hrefs to Alice's private resources
 - For example, to perform an action on Alice's account, it is possible to use **img** like this:
 2. Alice loads the page in her browser
 - Alice is authenticated to the bank's website, the browser sends Alice's authentication cookies with the request.
- Issues and Prevention
 - The bank site violates REST, i.e. overloading of GET for making actions
 - The bank should check HTTP **referer** header
 - It is a "blind" attack, Mallory does not see the result
 - To perform POST, current browsers today use **CORS protocol**

Cross-site Scripting Attack (XSS)

- Exploits a trust of a user in a website

- Example Scenario
 1. An attacker injects a code to a page
 2. A users executes the code in his/her browser's session
 3. The code provides information (cookies) to the attacker
 4. The attacker uses the cookies to access the user's data

XSS Examples

- Twitter in Sep 2010
 - *Injection of JavaScript code to a page using a tweet*
 - *You posted following tweet to Twitter*
 - *Twitter parses the link and wraps it with `<a>` element*
 - *See details at Twitter mouseover exploit [↗](#)*
- Other example: Google Contacts

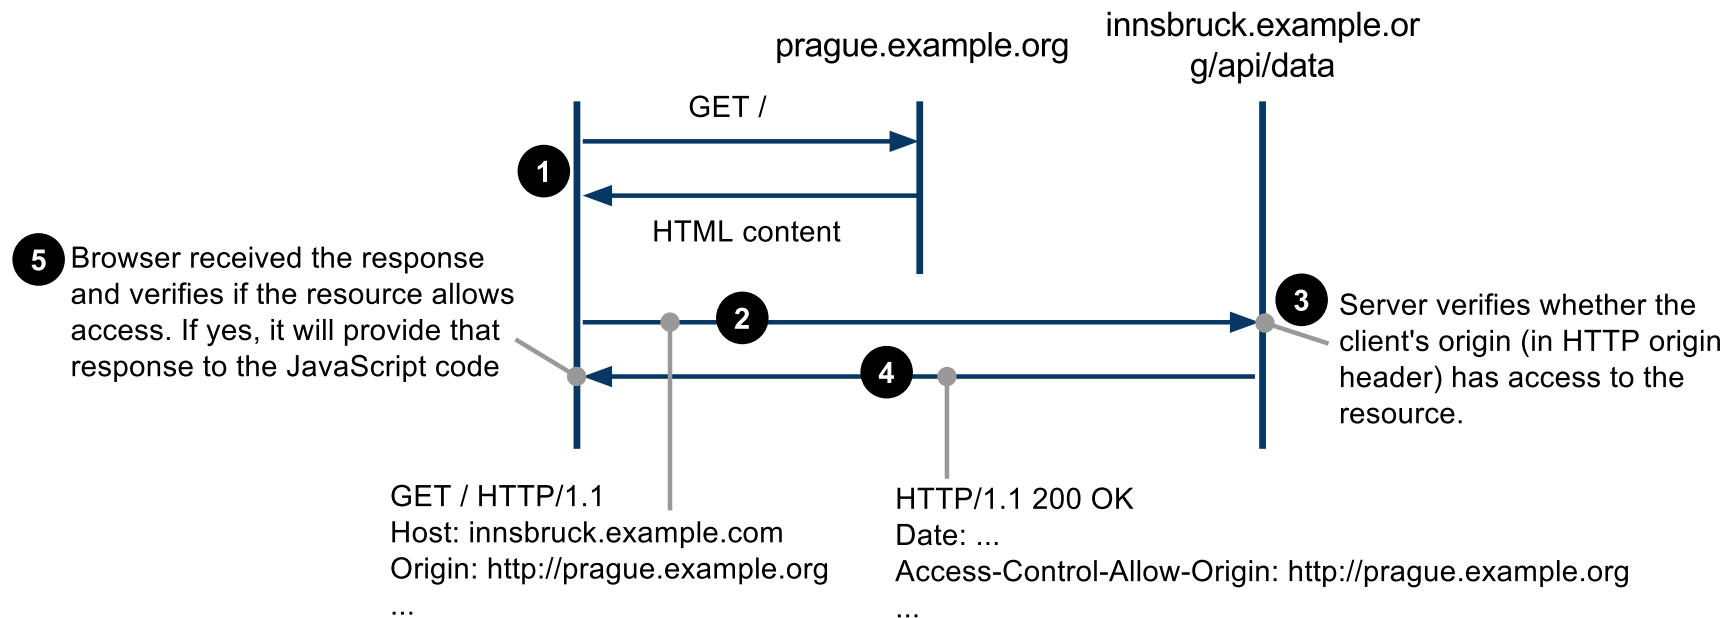

Overview

- Mashups and XHR
- Security Mechanisms
 - *Scripting Attacks*
 - *Cross-origin Resource Sharing Protocol (CORS)*
- JSON and JSONP

Overview

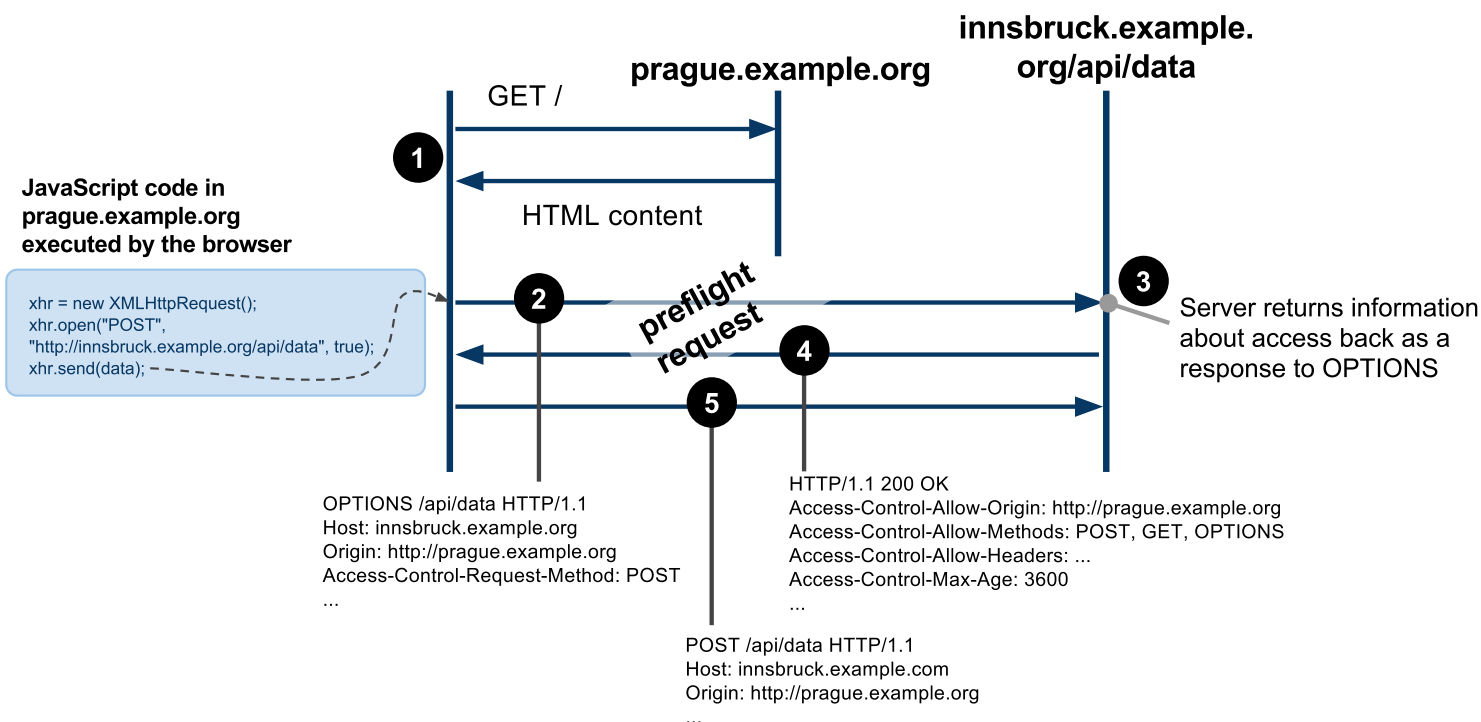

- Increasing number of mashup applications
 - *client-side mashups involving multiple sites*
 - *mechanism to control an access to sites from within JavaScript*
- Allow for **cross-site HTTP requests**
 - *HTTP requests for resources from a different domain than the domain of the resource making the request.*
- W3C specification, working draft
 - *see Cross-origin Resource Sharing* [↗](#)
 - *already browsers support it*
 - *see HTTP Access Control* [↗](#) *at Mozilla*

CORS Protocol – GET

- Read-only resource access via HTTP GET
- Headers:
 - **Origin** – identifies the origin of the request
 - **Access-Control-Allow-Origin** – defines who can access the resource
 - either the full domain name or the wildcard (*) is allowed.

CORS Protocol – other methods and "preflight"

- Preflight request queries the resource using **OPTIONS** method
 - requests other than *GET* (except *POST* w/o payload) or with custom headers
 - A browser should run preflight automatically for any XHR request meeting preflight conditions
 - The browser caches responses according to **Access-Control-Max-Age**

Overview

- Mashups and XHR
- Security Mechanisms
- JSON and JSONP

Recall: JSON

- JSON = JavaScript Object Notation
 - *Serialization format for data representation*
 - *Very easy to use in JavaScript*
 - *no need to use a parser explicitly*
 - *Also great support in many programming environments*
- Key constructs
 - ***object** is a collection of comma-separated key/value pairs:*
`{"name" : "tomas", "age" : 18, "student" : false, "car" : null}`
 - ***array** is an order list of values:*
`["prague", "innsbruck", 45]`
 - *can be nested: objects as values in an **array**:*
`[{ "name" : "tomas", "age" : 18 },
 { "name" : "peter", "age" : 19 }]`
 - *and the other way around: array as values in an **object**:*
`{ "cities" : ["prague", "innsbruck"],
 "states" : ["CZ", "AT"] }`
 - *A complete grammar see JavaScript Object Notation [🔗](#)*

JSON in JavaScript

- Native data format
- Responses of service calls in JSON
 - *Many support JSON, how can we load that data?*
- Example Request-Response

JSONP

- Service that supports JSONP
 - *allows to specify a query string parameter for a wrapper function to load the data in JavaScript code*
 - *otherwise the data cannot be used in JavaScript*
 - *they're loaded into the memory but assigned to nothing*
- Example
 - *if a resource at `http://someurl.org/json_data` returns then the resource at `http://someurl.org/json_data?_callback=loadData` returns*
- A kind of workaround for the same origin policy
 - *only `GET`, nothing else works obviously*
 - *no XHR, need to load the data through the dynamic `<script>` element*

JSONP in JavaScript

- JSONP example
 - *loads JSON data using JSONP by dynamically inserting `<script>` into the current document. This will download JSON data and triggers the script.*

JSON Vulnerability

- What it is
 - *JSON array data accessible via GET (normal access is via XHR)*
 - *Attacker may load the data in a **script**, redefine **Array** object, and assign the data to a variable.*
 - *Attacker's page with a script that you access:*
 - *your browser uses your cookies to load the resource*
- Prevention
 - *Using prefix in the data – the prefix makes the JSON data invalid; the client must strip the prefix before parsing the data as JSON*
 - *Use only POST for sensitive data*
