Humla v0.3

# Overview

- **Microservices Architecture**
- Docker
- Kubernetes

# Overview

- Emerging software architecture
  - *monolithic vs. decoupled applications*
  - *applications as independently deployable services*

A monolithic application puts all its functionality into a single process...

... and scales by replicating the monolith on multiple servers

A microservices architecture puts each element of functionality into a separate service...

... and scales by distributing these services across servers, replicating as needed.

# Major Characteristics

- Loosely coupled
  - *Integrated using well-defined interfaces*
- Technology-agnostic protocols
  - *HTTP, they use REST architecture*
- Independently deployable and easy to replace
  - *A change in small part requires to redeploy only that part*
- Organized around capabilities
  - *such as accounting, billing, recommendation, etc.*
- Implemented using different technologies
  - *polyglot – programming languages, databases*

# Overview

- Microservices Architecture
- Docker
  - *Overview*
  - *Image Layering*
  - *Working with Docker*
  - *Swarm*
- Kubernetes

# Overview

- Linux Containers
  - *Introduced in 2008*
  - *Allow to run a process tree in a isolated system-level "virtualization"*
  - *Use much less resources and disk space than traditional virtualization*
- Implementations
  - *LXC – default implementation in Linux*
  - **Docker Containers**
    - *Builds on new Kernel features: control groups (cgroups), kernel namespaces, union-capable file system (OverlayFS, AUFS, etc.)*
    - *A way to build, commit and share images*
    - *Build images using a description file called Dockerfile*
    - *Large number of available base and re-usable images*

# VM vs. Docker Containers

Containers are isolated, but share OS and, where appropriate, bins/libraries

# Docker Basic Terms

- Image
  - Basis for containers.
  - An image contains a union of layered filesystems stacked on top of each other.
  - An image does not have state and it never changes.
- Container
  - A runtime instance of a Docker image, a standard to "ship software".
- Docker Engine
  - The core process providing the Docker capabilities on a host.
- Docker Client
  - Interface that integrates with docker engine.
- Registry
  - A hosted service containing repository of images.
  - A registry provides a registry API to search, pull and push images.
  - Docker Hub is the default Docker registry.
- Swarm
  - A cluster of one or more docker engines.

# Docker Images

- Containers are made up of R/O layers via a storage driver (OverlayFS, AUFS, etc.)
- Containers are designed to support a single application
- Instances are ephemeral, persistent data is stored in bind mounts or data volume containers.

# Overview

- Microservices Architecture
- Docker
  - *Overview*
  - *Image Layering*
  - *Working with Docker*
  - *Swarm*
- Kubernetes

# Image Layering with OverlayFS

- OverlayFS
  - A filesystem service implementing a **union mount** for other file systems.
  - Docker uses **overlay** and **overlay2** storage drivers to build and manage on-disk structures of images and containers.
- Image Layering
  - OverlayFS takes two directories on a single Linux host, layers one on top of the other, and provides a single unified view.
  - Only works for two layers, in multi-layered images hard links are used to reference data shared with lower layers.

# Image Layers Example

- Pulling out the image from the registry

```
$ sudo docker pull ubuntu
```

```
Using default tag: latest  
latest: Pulling from library/ubuntu
```

```
5ba4f30e5bea: Pull complete  
9d7d19c9dc56: Pull complete  
ac6ad7efd0f9: Pull complete  
e7491a747824: Pull complete  
a3ed95caeb02: Pull complete  
Digest: sha256:46fb5d001b88ad904c5c732b086b596b92cfb4a4840a3abd0e35dbb6870585e4  
Status: Downloaded newer image for ubuntu:latest
```

- *Each image layer has its own directory under `/var/lib/docker/overlay/`.*
- *This is where the contents of each image layer are stored.*

- Directories on the file system

```
$ ls -l /var/lib/docker/overlay/
```

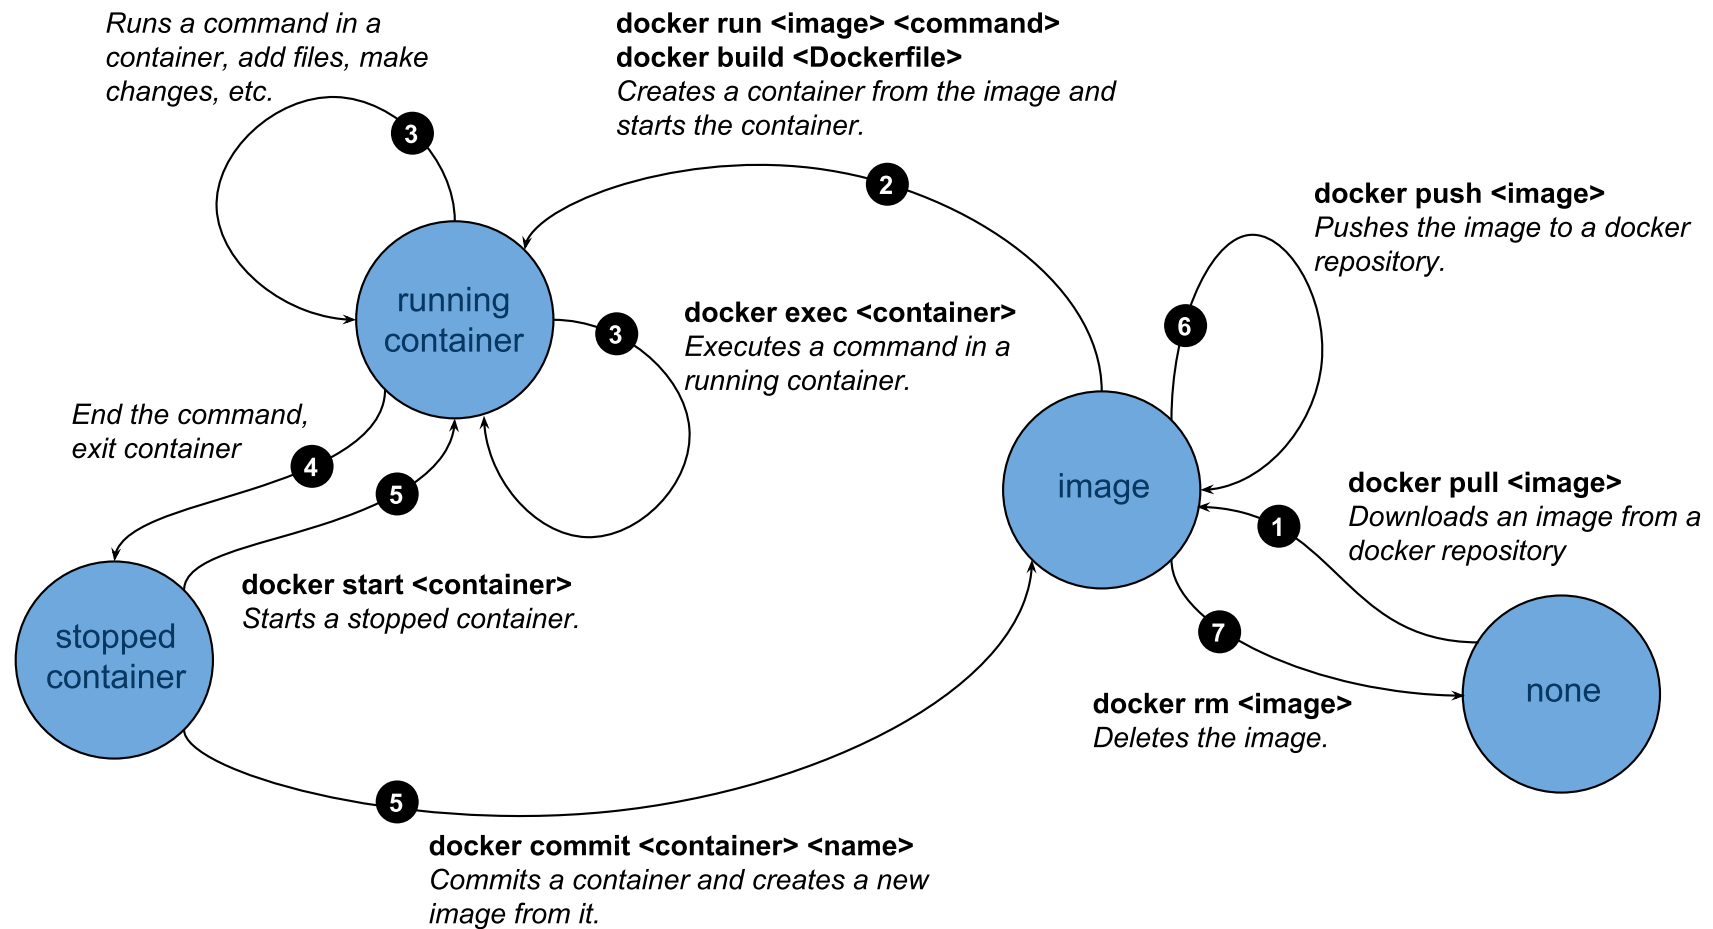

```
total 20  
drwx----- 3 root root 4096 Jun 20 16:11 38f3ed2eac129654acef11c32670b534670c3a06e483fce313d72e3e0a15baa

```

- *The organization of files allows for efficient use of disk space.*
- *There are **files unique to every layer** and **hard links to files shared with lower layers***

# Overview

# Docker Container Lifecycle State Diagram

# Commands (1)

**docker version**

*list current version of docker engine and client*

**docker search <image>**

*search for an image in the registry*

**docker pull <image[:version]>**

*download an image of a specific from the registry*

*if the version is not provided, the latest version will be downloaded*

**docker images**

*list all local images*

**docker run -it <image[:version]> <command>**

*start the image and run the command inside the image*

*if the image is not found locally, it will be downloaded from the registry*

*option -i starts the container in interactive mode*

*option -t allocates a pseudo TTY*

**docker ps [-as]**

*list all running containers*

*option -a will list all containers including the stopped ones.*

*option -s will list the container's size.*

## Commands (2)

`docker rm <container>`

*remove the container*

`docker rmi <image>`

*remove the image*

`docker commit <container> <name[:version]>`

*create an image from the container with the name and the version*

`docker history <image>`

*display the image history*

# Networking and Linking

- There are 3 docker networks by default
  - **bridge** – *container can access host's network (default)*
    - Docker creates subnet **172.17.0.0/16** and gateway to the network
    - When a container is started, it is automatically added to this network
    - All containers in this network can communicate with each other
  - **host** – *all host's network interfaces will be available in the container.*
  - **none** – *container will be placed on its own network and no network interfaces will be configured.*
- Custom Network configuration
  - *You can create a new network and add containers to it*
  - *Containers in the new network can communicate with each other but the network will be isolated from the host network*
- Linking containers (legacy)

```
$ docker run -d --name redmine-db postgres
$ docker run -it --link redmine-db:db postgres /bin/bash
root@c4b12143ebe8:/# psql -h db -U postgres
psql (9.6.1)
Type "help" for help.
postgres=# SELECT inet_server_addr();
postgres=# SELECT * FROM pg_stat_activity \x\g\x
```

# Networking Commands

`docker network ls`

*lists all available networks*

`docker network inspect <network-id>`

*Returns the details of specific network*

`docker network create --driver bridge isolated_nw`

*creates a new isolated network*

`docker run -it --network=isolated_nw ubuntu bin/bash`

*starts the container ubuntu and attaches it to the isolated network*

# Data Volumes

- Data Volume
  - *A directory that bypass the union file system*
  - *Data volumes can be shared and reused among containers*
  - *Data volume persists even if the container is deleted*
  - *It is possible to mount a shared storage volume as a data volume by using a volume plugin to mount e.g. NFS*
- Adding a data volume
  - `docker run -d -v /webapp training/webapp python app.py`  
*will create a new volume with name `webapp`,  
the location of the volume can be determined by using `docker inspect`.*
- Mount a host directory as a data volume
  - `docker run -d -v /src/webapp:/webapp training/webapp python app.py`  
*if the path exists in the container, it will be overlayed (not removed),  
if the host directory does not exist, the docker engine creates it.*
- Data volume container
  - *Persistent data to be shared among two or more containers*  
`docker create -v /dbdata --name dbstore training/postgres /bin/true`  
`docker run -d --volumes-from dbstore --name db1 training/postgres`  
`docker run -d --volumes-from dbstore --name db2 training/postgres`

# Dockerfile

- Dockerfile is a script that creates a new image

```
# This is a comment
FROM oraclelinux:7
MAINTAINER Tomas Vitvar <tomas@vitvar.com>
RUN yum install -q -y httpd
EXPOSE 80
CMD httpd -X
```

- A line in the Dockerfile will create an intermediary layer

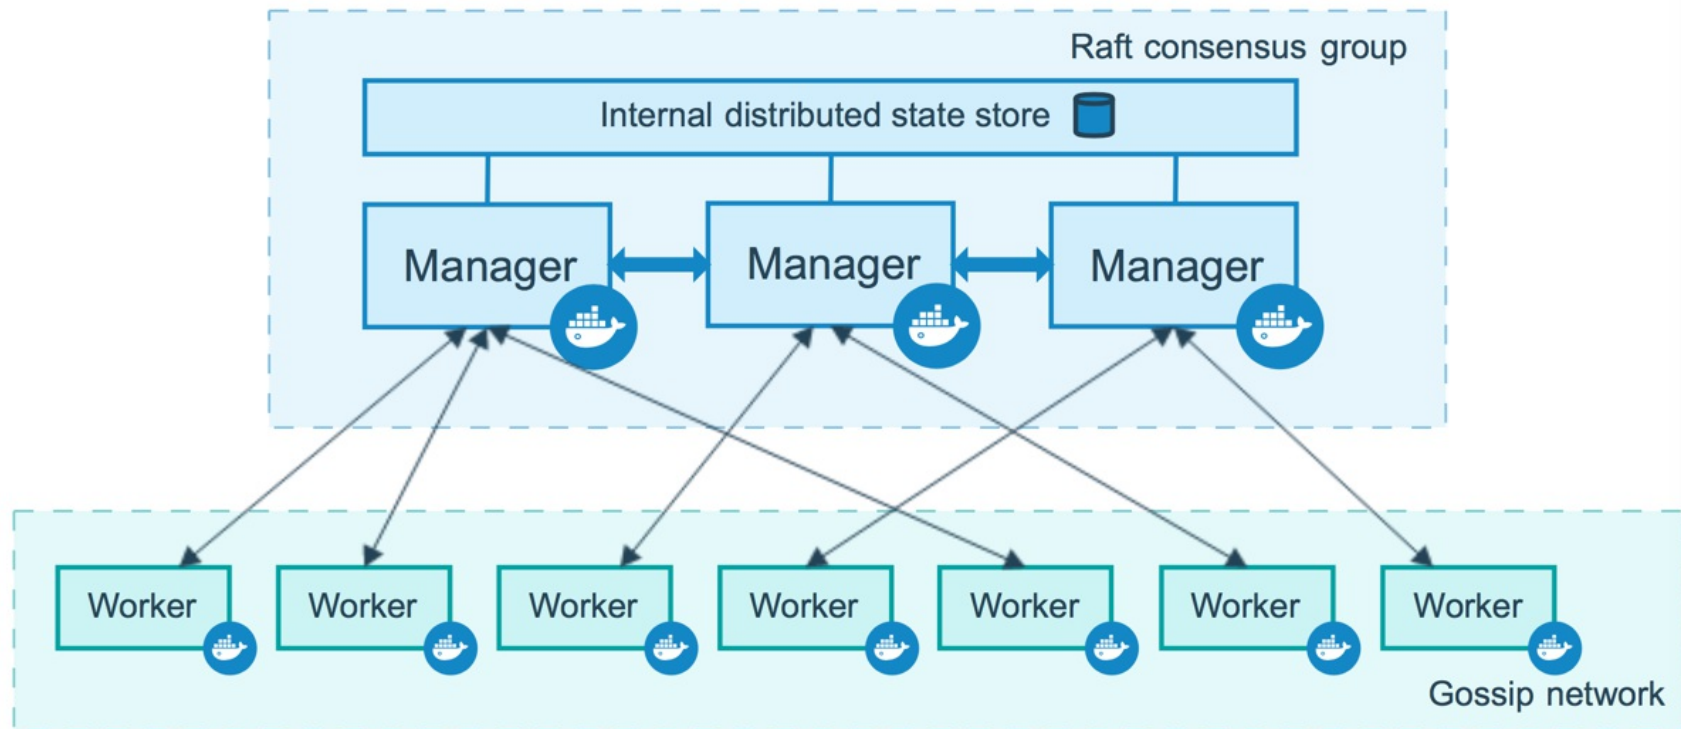

```
$ docker build -t tomvit/httpd:v1 .
Sending build context to Docker daemon 2.048 kB
Step 1 : FROM oraclelinux:7
---> 4c357c6e421e
Step 2 : MAINTAINER Tomas Vitvar <tomas@vitvar.com>
---> Running in 35feebb2ffab
---> 95b35d5d793e
Removing intermediate container 35feebb2ffab
Step 3 : RUN yum install -q -y httpd
---> Running in 3b9aee3c3ef1
---> 888c49141af9
Removing intermediate container 3b9aee3c3ef1
Step 4 : EXPOSE 80
---> Running in 03e1ef9bf875
---> c28545e3580c
Removing intermediate container 03e1ef9bf875
Step 5 : CMD httpd -X
---> Running in 3c1c0273a1ef
```

*If processing fails at some step, all preceeding steps will be loaded from the cache on the next run.*

# Overview

  - *Swarm*
- Kubernetes

# Swarm

# Overview

- Microservices Architecture
- Docker
- **Kubernetes**

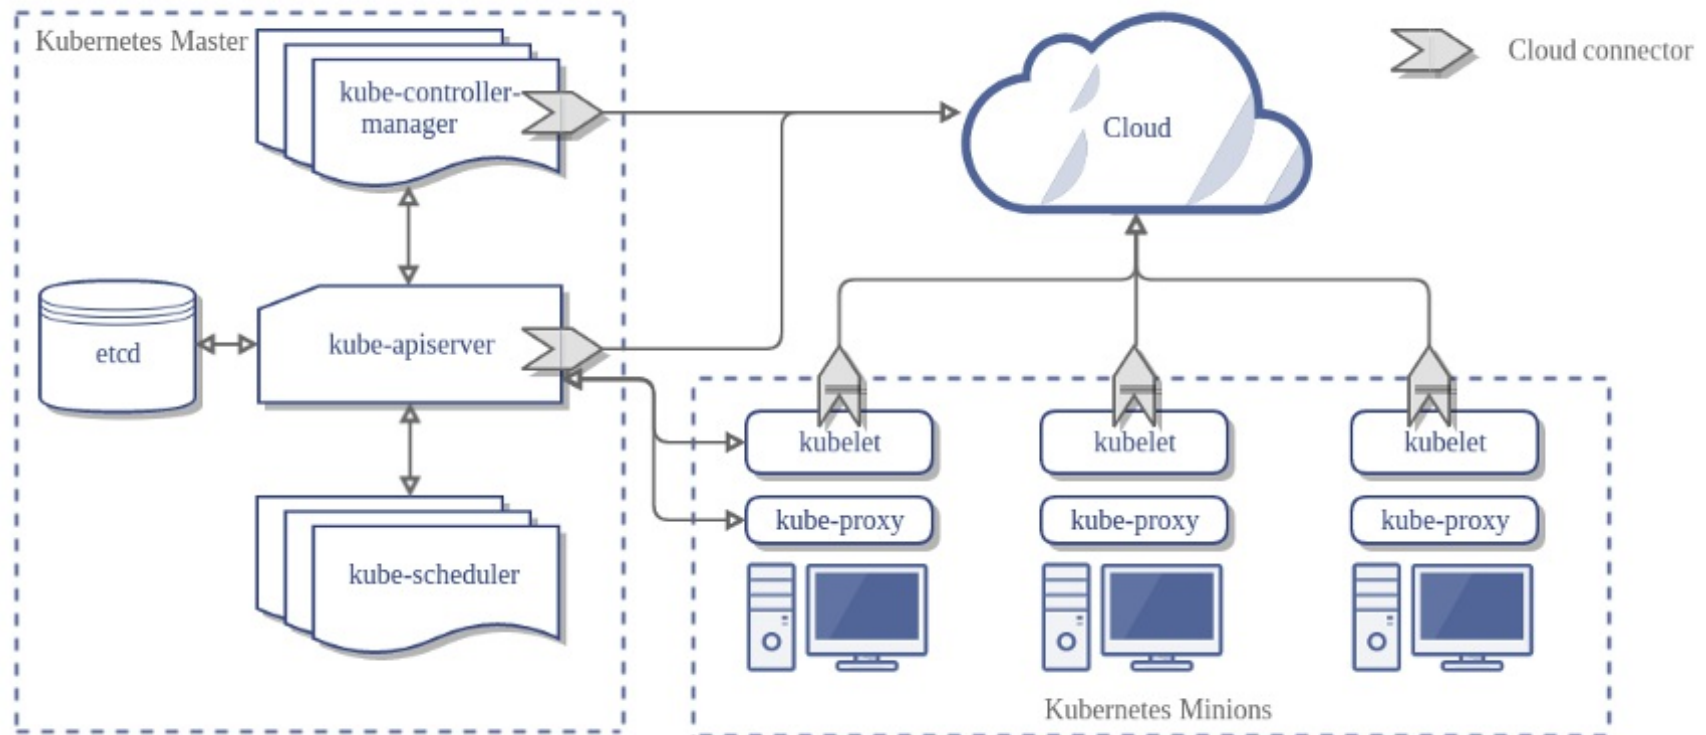

# Overview

- In your architecture...
  - Containers are atomic pieces of application architecture
  - Containers can be linked (e.g. web server, DB)
  - Containers access shared resources (e.g. disk volumes)
- Kubernetes
  - Automation of deployments, scaling, management of containerized applications across number of nodes
  - Based on Borg, a parent project from Google

# System Architecture

# Major Terms

- Node
  - *a worker machine in Kubernetes, previously known as a minion (a VM or physical machine). It uses **kubelet** and **kube-proxy** to communicate with the master and other nodes/services.*
- Master
  - *A node that manages the cluster of nodes.*
- Pod
  - *The basic building block of Kubernetes, one or more dependant containers.*
- Service
  - *A set of pods with rules allowing pods to talk to each other, such as:*
    - **NodePort** *exposes the pod under a cluster IP.*
    - **LoadBalancer** *exposes the pod for load balancing by external load balancer*
- Controllers
  - *Worker units to ensure a desired state, such as:*
    - **ReplicaSet** *ensures that a specified number of pod replicas are running.*
    - **Deployment** *manages ReplicaSets, provides declarative updates to pods.*
    - **StatefulSet** *manages deployment and scaling of a set of Pods.*
    - **DaemonSet** *ensures that all (or some) Nodes run a copy of a Pod.*

# Features

- Automatic binpacking
  - *Automatically places containers onto nodes based on their resource requirements and other constraints.*
- Horizontal scaling
  - *Scales your application up and down with a simple command, with a UI, or automatically based on CPU usage.*
- Automated rollouts and rollbacks
  - *Progressive rollout out of changes to application/configuration, monitoring application health and rollback when something goes wrong.*
- Storage orchestration
  - *Automatically mounts the storage system (local or in the cloud)*
- Self-healing
  - *Restarts containers that fail, replaces and reschedules containers when nodes die, kills containers that don't respond to user-defined health checks.*
- Service discovery and load balancing
  - *Gives containers their own IP addresses and a single DNS name for a set of containers, and can load-balance across them.*

# Demo

- Environment Setup

`minikube` – a local virtual machine (running a master and a single node)

`kubectl` – CLI to access Kubernetes cluster

- Steps

1. create `hello-node` app in `node.js` and test it [see [server.js](#)]

`node server.js`

2. create docker image for the app [see [Dockerfile](#)]

`docker build -t hello-node:v1 .`

3. deploy the app to Kubernetes by using `kubectl`

`kubectl run hello-node --image=hello-node:v1 --port=8080`

4. Expose the app as a load balancer service.

`kubectl expose deployment hello-node --type=LoadBalancer`

5. Explore the app in minikube dashboard.

`minikube dashboard`

6. Fire requests at the service and count them [see [test.sh](#)]

`./test.sh.`

7. Change the number of replicas by using the dashboard or `kubectl`.
