REST Core Principles

- REST architectural style defines constraints
 - if you follow them, they help you to achieve a good design, interoperability and scalability.
- Constraints
 - Client/Server
 - Statelessness
 - Cacheability
 - Layered system
 - Uniform interface
- Guiding principles
 - Identification of resources
 - Representations of resources and self-descriptive messages
 - Hypermedia as the engine of application state (HATEOAS)

- Uniform Interface
 - Basic operations
 - Handling Errors
- Asynchronous Communication
- Implementing a RESTful Service
- Advanced Design Issues

Uniform Interface

- Uniform interface = finite set of operations
 - Resource manipulation
 - → CRUD Create (POST/PUT), Read (GET), Update (PUT/PATCH), Delete (DELETE)
 - operations are not domain-specific
 - → For example, GET /orders and not getOrders()
 - → This reduces complexity when solving interoperability
- Integration issues examples

Safe and Unsafe Operations

- Safe operations
 - Do not change the resource state
 - Usually "read-only" or "lookup" operation
 - Clients can cache the results and refresh the cache freely
- Unsafe operations
 - May change the state of the resource
 - Transactions such as buy a ticket, post a message
 - Unsafe does not mean dangerous!
- Unsafe interactions and transaction results
 - POST response may include transaction results
 - → you buy a ticket and submit a purchase data
 - → you get transaction results
 - → and you cannot bookmark this..., why?

Idempotence

- Idempotent operation
 - Invoking a method on the same resource always has the same effect
 - Operations GET, PUT, DELETE
- Non-idempotent operation
 - Invoking a method on the same resource may have different effects
 - Operation POST
- Effect = a state change
 - recall the effect definition in MDW

- Uniform Interface
 - Basic operations
 - Handling Errors
- Asynchronous Communication
- Implementing a RESTful Service
- Advanced Design Issues

GET

• Reading

- GET retrieves a representation of a state of a resource
 - > GET /orders HTTP/1.1
 - > Accept: application/xml
 - < HTTP/1.1 200 OK
 - < Content-Type: application/xml
 - <
 - < ...resource representation in xml...
- It is read-only operation
- It is safe
- It is **idempotent**
- GET retrieves different states over time but the effect is always the same, cf. resource state hence it is idempotent.
- Invocation of GET involves content negotiation

PUT

- Updating or Inserting
 - PUT updates a representation of a state of a resource or inserts a new resource

```
> PUT /orders/4456 HTTP/1.1
> Content-Type: application/xml
>
> <order>...</order>
< HTTP/1.1 CODE</pre>
```

- where CODE is:
 - → 200 OK or 204 No Content for updating: A resource with id 4456 exists, the client sends an updated resource
 - → 201 Created for inserting: A resource does not exist, the client generates the id 4456 and sends a representation of it.
- It is **not safe** and it is **idempotent**

POST

- Inserting
 - POST inserts a new resource
 - A server generates a new resource ID, client only supplies a content and a resource URI where the new resource will be inserted.

```
> POST /orders HTTP/1.1
> Content-Type: application/xml
>
> <order>...</order>
< HTTP/1.1 201 Created
< Location: /orders/4456</pre>
```

- It is not safe an it is not idempotent
- A client may "suggest" a resource's id using the Slug header
 - → Defined in AtomPub protocol 🗗

DELIEFTE

- Deleting
 - DELETE deletes a resource with specified URI
 - > DELETE /orders/4456 HTTP/1.1
 - < HTTP/1.1 CODE
 - where CODE is:
 - → 200 OK: the response body contains an entity describing a result of the operation.
 - \rightarrow 204 No Content: there is no response body.
 - It is **not safe** and it is **idempotent**
 - → Multiple invocation of DELETE /orders/4456 has always the same effect the resource /orders/4456 does not exist.

Other

- HEAD
 - same as **GET** but only retrieves HTTP headers
 - It is **safe** and **idempotent**
- OPTIONS
 - queries the resource for resource configuration
 - It is **safe** and **idempotent**

- Uniform Interface
 - Basic operations
 - Handling Errors
- Asynchronous Communication
- Implementing a RESTful Service
- Advanced Design Issues

Types of Errors

- Client-side status code 4xx
 - 400 Bad Request
 - → generic client-side error
 - → invalid format, such as syntax or validation error
 - 404 Not Found
 - → server can't map URI to a resource
 - 401 Unauthorized
 - → wrong credentials (such as user/pass, or API key)
 - → the response contains WWW-Authenticate indicating what kind of authentication the service accepts
 - 405 Method Not Allowed
 - → the resource does not support the HTTP method the client used
 - → the response contains Allow header to indicate methods it supports
 - 406 Not Acceptable
 - → so many restrictions on acceptable content types (using Accept-*)

Types of Errors (Cont.)

- Server-side status code 5xx
 - 500 Internal Server Error
 - → generic server-side error
 - → usually not expressive, logs a message for system admins
 - 503 Service Not Available
 - → server is overloaded or is under maintenance
 - *→ the response contains* Retry-After *header*

Use of Status Codes

• Service should respect semantics of status codes!

- Client must understand the semantics of the response.
- This breaks loose coupling and reusability service principles
- The response should be:

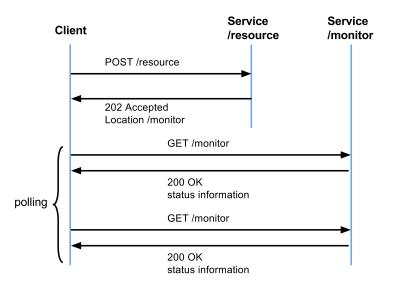

```
< HTTP/1.1 401 Unauthorized < ...
```

< ...optional text describing the error...

- Uniform Interface
- Asynchronous Communication
- Implementing a RESTful Service
- Advanced Design Issues

Asynchronous Communication

- Recall asynchronous communication from MDW
- Asynchronous communication in HTTP
 - Server cannot establish a connection, always clients need to
 - → clients are browsers behind firewalls

Asynchronous and Polling/Pushing

- Submit request for processing
 - Always through HTTP request and 202 Accepted response and Location header with a monitor resource
 - Methods: PUT, POST, DELETE
- Getting the status from the monitor resource
 - -polling a client periodically checks for changes via GET
 - → *Most natural solution, not a real-time solution*
 - -pushing a server pushes changes back to the client
 - \rightarrow Part of real-time Web efforts
 - More details in Lecture 8: Protocols for the Realtime Web

- Uniform Interface
- Asynchronous Communication
- Implementing a RESTful Service
 - Basic Implementation
- Advanced Design Issues

Service Description

• Example service: Oder processing

https://github.com/tomvit/w20/tree/master/examples/restful-service

```
* the service provides three operations: 'open', 'add', 'close'
    * operation 'open' opens the order
      - input: none
      - output: text informing that the order was opened
   * operation 'add' adds an item to the order
      - input: an item name, the syntax is [0-9A-Za-z\-]+
      - output: text informing that the item was added to the order
   * operation 'close' closes the order and returns all items in the order
11
      - input: none
12
      - output: list of all items previously added to the order
13
   * the public process is: S0--open--S1, S1--add--S1, S1--close--S0, where
15
     S0, S1 are states such that S0 = order is closed, and S1 = order is opened.
17
   * protocol is HTTP, RESTful service
    running at ec2.vitvar.com, tcp/9900
```

- Basic steps to define a RESTful service
 - 1. identify resources and URIs
 - 2. specify resources' representations
 - 3. **define service operations** (methods and status codes)

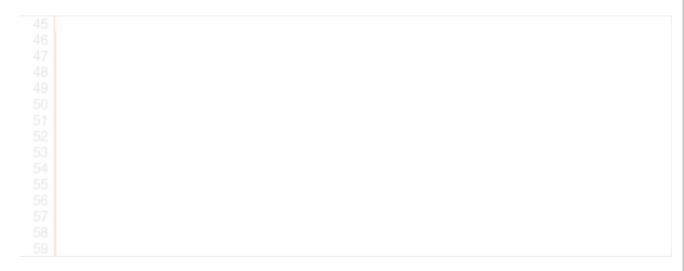

- Uniform Interface
- Asynchronous Communication
- Implementing a RESTful Service
 - Basic Implementation
- Advanced Design Issues

Resources, URIs and Representations

- There are three resources
 - Resource /orders is a container of all orders
 - Resource /orders/{order-id} is an order with resource id order-id.
 - Resource /orders/{order-id}/{item-id} is an item that belongs to the order order-id and that has a resource id item-id.
- Structure
 - /orders
 - \rightarrow list of all orders
 - -/orders/{order-id}
 - → status, order id, list of all items in the order
 - -/orders/{order-id}/{item-id}
 - → item id, name, price
- Resource representations
 - We define representations in JSON

Open Order

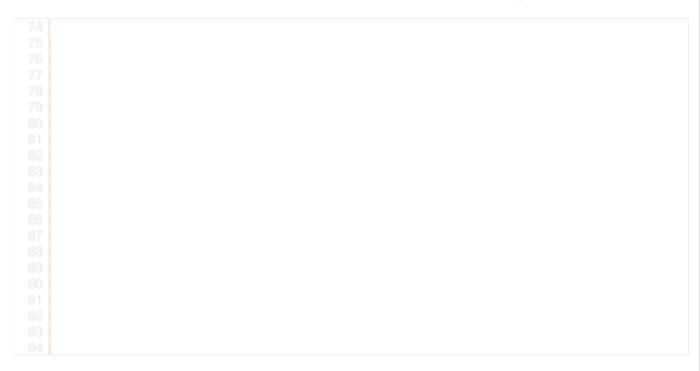

- To open an order
 - Insert a new order to Jorders using POST
 - Set the new order's status to "open"

- → storage.getOrderSeqId() returns the order ID
- → storage.orders (line 37) is an array of all orders in a storage

Add Item to Order

- To add an item to the order
 - Insert a new item to the order /orders/{order-id} using POST

Close Order

- To close an order
 - Update the status of the order /orders/{order-id} using PUT

```

107

108

109

110

111

112

113

114

115
```

Other Operations

- To get, delete an order and get, delete and update an item
 - Delete an order /orders/{order-id} using DELETE
 - Get an order's item /orders/{order-id}/{item-id} using GET
 - Update an order's item /orders/{order-id}/{item-id} using PUT
 - Delete an order's item /orders/{order-id}/{item-id} using DELETE
- Other methods are not allowed
 - Send 405 Not Allowed status with Allow header to indicate which methods are allowed on a resource

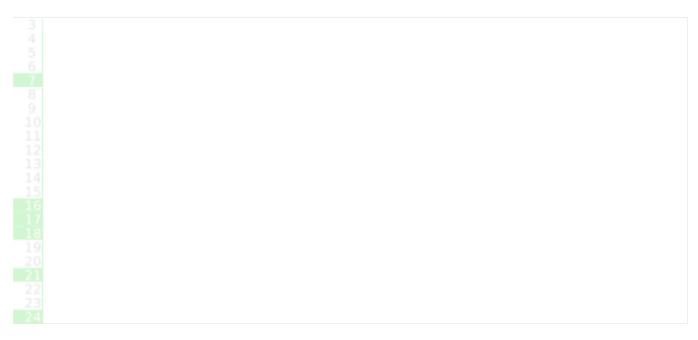

```
if (method != "GET" && method != "PUT" && method != "POST" && method != "DELETE")
return {
    status: "405", // method not allowed
    headers : { "Allow" : "GET, PUT, POST, DELETE" }
};
```

- Implement the remaining methods listed above

Testing

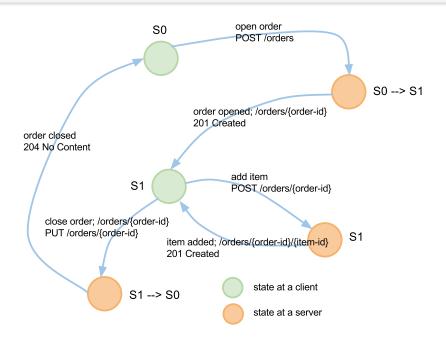

• Test the service using a bash script test.sh

- Run service and test it using the test.sh script.

RESTful Public Process

• Note

- client, service communicate through metadata and representations
- There is no need for a stateful server

- Uniform Interface
- Asynchronous Communication
- Implementing a RESTful Service
- Advanced Design Issues

Respect HTTP Semantics

- Do not overload semantics of HTTP methods
 - For example, GET is read-only method and idempotent
 - REST Anti-pattern:

```
GET /orders/?add=new order
```

- \rightarrow This is not REST!
- → This breaks both safe and idempotent principles
- Consequences
 - Result of GET can be cached by proxy servers
 - They can revalidate their caches freely
 - You can end up with new entries in your storage without you knowing!
- The same is true for other methods

Change Order Status

- status property of /orders/{order-id} resource
 - reflects a state of the process
 - No need to use a stateful service, state is communicated through the order representation
- How do you implement a canceling an order?
 - You can delete it using DELETE
 - But you may want to cancel it in order to:
 - → maintain a list of canceled orders
 - → have a possibility to "roll-back" canceled orders

DELETE to cancel

- A bad solution to cancel the order
 - to cancel with DELETE

DELETE /orders/3454/?cancel=true

- you overload the meaning of DELETE
- you violate the uniform interface principle
- Always ask a question:
 - Is the operation a state of the resource?
 - if yes, the operation should be:
 - → modeled within the data format
 - → or as a separated resource (sub-resource)
- No verbs in path and query components!
 - /cancelOrder, /orders/{order-id}/?action=delete, etc.
 - Verbs in URIs indicate that a resource is actually an operation!

PUT to cancel

- A RESTful solution to cancel an order
 - 1. first, have an order's status
 - as part of the Order representation format
 - we extend "open" and "close" with "cancel"
 - 2. Use PUT to cancel an order

```
1  > PUT /orders/{order-id}
2  > Content-Type: application/json
3  >
4  > { "status" : "cancel" }
5
6  < HTTP/1.1 204 No Content</pre>
```

- Clean-up all cancelled orders
 - you can have a resource "all valid orders": /orders/valid
 (~ all orders that are not canceled)
 - → GET /orders/valid will return all non-canceled orders

Lecture 3: Uniform Interface, CTU Summer Semester 2016/2017, @TomasVitvar

Evaluation

- How "good" is our Order Book service?
 - Analysis of the service by service characteristics (see MDW for details) and HTTP principles.

Principle Loose Coupling		Comment		
	+	Uses standard response codes.		
	+	Uses representation of resources and HTTP Location header to implement the public process.		
	_	Does not use hypermedia; client needs to construct links for some resources.		
	+	Properly models resource URIs and resource IDs; they have hierarchical nature; does not use verbs.		
	+	Respects semantics of HTTP methods and extensively uses them.		
Reusability	+	Unforeseen clients will likely use the service as the application state is communicated through HTTP.		
	_	Only offers one representation format (JSON).		
Contracting and Discoverability	-	Does not describe content type nor public process such as by using Internet Media Types.		
Composability	+	Does not obstruct composition.		
Abstraction	+	Service description can be implemented by various implementation technologies.		
Encapsulation	+	Distinguishes interface from implementation, processing logic is not exposed to
